ABSTRACT

Telecommunication networks can be seen as the stacking of several layers like, for instance, IP-over-Optical networks. This infrastructure should have sufficient capacities to route some demands between their origindestination nodes. In this paper we consider the Capacitated Multi-Failure Survivable Network Design problem. We study two variants of this problem with simple and multiple capacities. We give two multicommodity flow formulations for each variant of this problem and describe some valid inequalities. In particular, we characterize valid inequalities obtained using Chvatal-Gomory procedure from the well known Cutset inequalities. We show that some of these inequalities are facet defining. We discuss separation routines for all the valid inequalities. Using these results, we develop a Branch-and-Cut algorithm and a Branch-and-Cut-and-Price algorithm for each variant and present extensive computational results.

1. Introduction

In the past years, telecommunication networks have seen an important development with the advances in optical technologies and the explosive growth of the Internet. Also the data traffic has increased dramatically and has now surpassed voice traffic in volume. Using the new optical technologies, different systems allow a very large increase of data transportation capacity and the transfer of almost illimitated quantities of information. Hence, in the event of a failure, a big amount of traffic may be lost. As a consequence, telecommunication networks must have a survivable topology, that is to say a configuration of their nodes and the links between the nodes that permits the communication to be restored and the network to remain functional in the event of a failure. For this, network survivability has become a major objective in the design of telecommunication networks.

Data networks have always been analyzed, described and managed in a multilayer structure. Indeed, it is quite natural to assume that the more elaborate functionalities of a network rely on a set of simple ones provided by some lower layer. This is in particular the case of modern telecommunication networks where different technologies (SDH/ SONET, WDM, Gigabit Ethernet, IP, ...) are combined in various ways on successive layers. From a practical point of view, this means that, in order to carry its traffic on some layer, the network may need to use a lower-level technology. Then several layers can be piled up in order to have an operational network offering a variety of services. The advantage of this is that each technology can be used for its most favorable features. Moreover, each technology is characterized by a certain range of traffic rates. The drawback, however, is that each technology, and hence each layer, manages its own routing control scheme independently from the others, and addresses its own survivability issues. Ghani et al. (2008) present a survey of the various new and heterogeneous infrastructures in telecommunication networks and address the challenges on these new technologies in the area of survivability. In Pacharintanakul and Tipper (2009), Pacharintanakul and Tipper investigate survivability strategies for IP-over-WDM networks in a multilayer framework where traffic originates at each layer. They present optimization models and experimental results using Cplex.

The capacities of a given layer correspond to the (worst-case) traffic demands that must be routed on the layer just below. The process of determining the capacities to install on the different layers of a network, usually called *dimensioning*, often reduces to a succession of multicommodity flow problems (A multicommodity flow is a superposition of different flows between origine-destination pairs). Usually there is an empirical relation between these problems, and the whole dimensioning problem is never treated in an optimal way. As a consequence, in a network design problem, reliability is considered layer

by layer without tackling the redundancy and the non-optimality yielded by the multilayer structure. Moreover, a failure in the network can be handled by several successive layers. This results in a potential huge global over-provisioning of resources, each layer protecting in turn the ones above. However the relation between technologies used in the different layers is usually complex, and does not permit to efficiently correlate the control of the successive layers. In consequence, the solution provided for this multilayer survivability problem usually consists of an over protection of the whole network. But this may be very costly and sometimes not efficient.

The introduction of new protocols in telecommunication (like MPLS and GMPLS) (Zouganeli, 2001) gives a new trend for multilayer data networks. These new systems provide a common signaling and routing framework between the different layers, and they do not restrict the way these layers work together. This evolution is yielding new survivability issues in multilayer networks. In Voge (2006), Voge studies different problems about the multilayer telecommunication networks based on MPLS and GMPLS. Bigos, Cousin, Gosselin, Foll, and Nakajima (2007) study different options for the survivability implementation in MPLS over Optical Transport Networks. They give an integer linear programming formulation for the underlaying optimization problem.

In this paper we introduce a multilayer capacitated survivable network design problem that may be of practical interest for the design and the dimensioning of IP-over-optical networks. These networks, based on the GMPLS technology, consist of two layers, the IP (client) layer and the optical (transport) layer. The two layers are represented by two graphs G_1 and G_2 , respectively. If a link *e* in the optical network is cut, a set of edges F_e of the IP network may be affected. We suppose that a set of traffic demands must be routed in the IP network between some origin-destination pairs. We also suppose that two types of capacities can be installed in the IP network in order to route the demands. If a cost is associated with each type of capacity, the problem is to determine the minimum cost set of capacities to be installed in the IP network so that the traffic demands can be routed in the event of any failure in the IP network, that is to say in any subgraph $G_1 \setminus F_a$ obtained from G_1 , by deleting F_e , for all edge e of G_2 . We provide mixed integer programming formulations for this problem and discuss Branch-and-Cut and Branch-and-Cut-and-Price algorithms.

Survivability and dimensioning have already been studied in the literature for multilayer networks. In particular, heuristic approaches have been proposed. In Gouveia, Patrício, de Sousa, and Valadas (2003) and Gouveia, Patrício, and de Sousa (2008), Gouveia and Patrício study the design of MPLS-over-WDM networks. They address the dimensioning subject to some path constraints in the WDM layer and hop constraints in the MPLS layer. They give an integer programming formulation and devise a heuristic technique based on that formulation. In Ricciato, Salsano, Belmonte, and Listanti (2002), Ricciato et al. consider the problem of off-line configuration of MPLS-over-WDM networks under time-varying offered traffic. They present a mixed integer programming formulation for the problem and discuss heuristic approaches. Binh and Ly (2012) propose a genetic algorithm for solving a multilayer survivable optical network design problem. A genetic based algorithm is also proposed by Ruiz et al. (2011) for survivable IP/MPLSover-WSON multilayer network optimization. There are also some recent works carried out on two-layered network design with or without dimensioning. Orlowski and Wessäly (2004) describe a general integer linear programming model for the design of multilayer telecommunication network design problem which integrates hardware, capacity, routing and grooming decisions. They give also a sketch of an algorithmic approach. Orlowski, Koster, Raak, and Wessäly (2006) develop three primal heuristics to be called in a Branch-and-Cut algorithm to solve the problem with two layers. Koster, Orlowski, Raack, Baier, and Engel (2008) consider a planning problem arising in SDH/ WDM multilayer telecommunication network design. They present a mixed-integer programming formulation and a Branch-and-Cut approach with cutting planes based on either of the two layers. Knippel and Lardeux (2007) study heuristic and exact algorithms based on metric inequalities for a multilayer network design problem (see also Lardeux, 2005). Mattia (2013) considers this problem from a polyhedral point of view. She presents valid inequalities and describes conditions for theses inequalities to be facet defining. Fortz and Poss (2009) develop a Branch-and-Cut algorithm to solve the Benders decomposition of the problem. As a consequence, they improve the constraints generation method used by Knippel and Lardeux (2007). Borne, Gabrel, Mahjoub, and Taktak (2011) study a survivability problem in multilayer IP-over-optical networks. They formulate the problem in terms of 0–1 linear program based on path variables and propose a Branch-and-Price algorithm.

The first major survivability requirement used in telecommunication networks is the so-called 2-connectivity. That is there must exist at least two edge-disjoint paths between every pair of nodes in the network. This implies that the network remains connected in the event of any single edge failure. The problem of finding a minimum cost 2-edge connected subgraph has been extensively investigated in the past decades (Barahona & Mahjoub, 1995; Grötschel, Monma, & Stoer, 1995; Kerivin, 2000; Kerivin & Mahjoub, 2005; Mahjoub, 1994; Stoer, 1992).

Dahl and Stoer (1998) present a cutting plane approach for solving the MULTIcommodity SUrvivable Network design problem (MULTISUN problem). This consists, given point-to-point traffic demands in a network, in finding minimum cost capacities that permit the routing of the given demands. The possible capacity choices on each edge give rise to a discrete cost function. Another problem called the Network Loading Problem (NLP) plays a central role in the design of telecommunication networks. It is a special case of the MULTISUN problem. For the NLP, a single type of capacitated facility is considered, and each link can be assigned one or several types of capacities in such a way that the network can carry given point-to-point demands at minimum cost. Barahona (1996) studies this problem in the both unsplittable and splittable cases that is when the flow of each commodity is carried by a single path or when it could use several paths. He proposes a separation algorithm for the so-called cut inequalities, which seem to play a central role for solving the problem. In Magnanti, Mirchandani, and Vachani (1993) Magnanti et al. study the polyhedral structure of two core subproblems of the NLP. And in Magnanti, Mirchandani, and Vachani (1995) they discuss a further problem, called the Two-Facility capacitated network Loading Problem (TFLP), in which two types of capacities are considered.

The paper is organized as follows. In the following section we discuss the IP-over-optical networks and the interaction between the different layers. We present a multilayer survivable network design problem with capacity constraints, called the multilayer capacitated survivable IP network design problem. We describe two versions of this problem: with and without multiple edges. We give mixed integer programming formulations for this problem. In Section 3, we study the associated polytopes. We identify a few classes of valid inequalities and describe conditions for theses inequalities to be facet defining. In Section 4, we describe the Branch-and-Cut algorithms and Branch-and-Cut and-Price algorithms for the problem. Our computational results are presented and discussed in Section 5. In Section 6, we give some concluding remarks.

2. The Capacitated Multi-Failure Survivable Network Design Problem

2.1. Multilayer telecommunication networks

Telecommunication networks are now moving toward a model of high-speed routers interconnected by intelligent optical core networks. Moreover, there is a general consensus that the control plan of the optical networks should utilize IP-based protocols for dynamic provisioning and restoration of lightpaths (Bradner, 1995; Jensen, 2001; Postel, 1981a, 1981b, 1981c).

Fig. 1. An IP-over-optical network.

The optical network consists of multiple switches (also called Optical Cross-Connects (OXC)) interconnected by optical links. The IP and optical networks communicate through logical control interfaces called User-Network-Interfaces (UNI). The optical network essentially provides point-to-point connectivity between routers in the form of fixed bandwidth paths called *lightpaths*. These lightpaths define the topology (the structure of the network given by the nodes and the possible links between the nodes) of the IP network.

Each router in the IP network is connected to at least one of the optical switches. Moreover to each link between two routers in the IP network corresponds a routing path in the optical one between two switches corresponding to these routers. This routing path is used for routing the traffic between the two switches. The set of routing paths is also referred to as the *routing* of the network. Fig. 1 shows an IP-over-optical network. The IP network has four routers $R_1, ..., R_4$ and the optical network has seven switches $S_1, ..., S_7$. Only the optical switches $S_1, ..., S_4$ communicate with one router through the UNI.

Using this infrastructure of telecommunication networks give rise to survivability issues. For example consider the IP-over-optical network given in Fig. 1. Suppose that the link R_1-R_2 of the IP network corresponds to the optical path S_1-S_2 , and the link R_1-R_3 corresponds to the path $S_1-S_2-S_6-S_3$. Here, the network is not survivable to single link failures. For instance, if the optical link S_1-S_2 fails, then the links in the IP network R_1-R_2 and R_1-R_3 are cut, and therefore the router R_1 is no more connected to the rest of the routers. As a consequence, survivability strategies have to be considered. If the transport network is fixed, one has to determine the suitable client network topology for the network to be survivable.

In addition to the survivability aspect, it is sometimes necessary to install capacities on the IP network in order to route commodities between some routers. In this paper we shall discuss this problem which considers simultaneously both the survivability and the dimensioning of the IP network when the transport network is fixed.

2.2. The problem

The first major survivability requirement used in telecommunication networks is the 2-connectivity. That is there must exist at least two edge-disjoint paths between every pair of nodes in the network. This assumption, that only one edge may fail at a time, is based on the naive idea that the links in the network are independent and no equipment can be commonly used by two distinct links. However, this is not the case, for instance, for the IP-over-optical networks, when the optical layer is taken into account in the management of the IP network.

Indeed, an edge of the optical network may appear in several paths supporting distinct edges. In consequence, the failure of an edge in the optical network may affect several optical paths, and hence the edges of the client network corresponding to these paths. As a result, several edges may fail at the same time in the IP layer (such a group of links is usually referred to as a Shared Risk Link Group, or SRLG).

The multilayer survivable IP network design problem (MSIPND problem) introduced by Borne, Gourdin, Liau, and Mahjoub (2006) consists in finding the set of links to be installed in the IP network so that if a failure occurs on an optical link, the IP subnetwork obtained by removing the corresponding edges is connected.

In our problem, we can install capacities of 2.5 Gbits or 10 Gbits on any link of the IP network. Moreover, we consider that each time a certain capacity is installed from a router R_1 to a router R_2 , one has to install the same capacity from R_2 to R_1 .

Consequently, a more realistic model which has to be investigated, would consist in setting up capacities with a minimum cost to the client network that allows a multicommodity flow which satisfies the capacities for any simple edge failure in the transport network.

In this paper we consider this problem. More precisely, we consider the overlay model where the IP and the optical networks are separated. We suppose that the topology and the routing of the optical network are fixed and satisfy some survivability requirements. Here the routing is the way the traffic is routed in the network. It corresponds to a set of paths between the origin-destinations which carry the traffic. We also suppose that the optical network is already dimensioned and has enough capacity to convey the network traffic. So here, we will focus on the management of the logical layer. We suppose that a set of IP routers (resp. optical switches) is given as well as the possible links between the routers (resp. switches). As the routing of the optical network is known, one can determine for each optical link e, the set of edges of the IP network that may be affected if e is cut. We also suppose that some traffic demands, also called commodities, have to be routed between some pairs of origin-destination nodes. Each demand is of a certain amount. If a certain cost is associated with each type of capacity on each edge of the IP network, the Capacitated Multi-Failure Survivable Network Design problem (SND-MF problem) is to find the minimum cost set of links to be installed in the IP network and the capacities to be installed on these links so that if a failure occurs on an optical link, the IP subnetwork obtained by removing the corresponding edges allows a routing of the demands which satisfies the capacities. In the rest of the paper we will also use the term *facility* to designate either the capacity 2.5 Gbits or 10 Gbits that will be used in the network.

We consider two variants of the problem: the multiple SND-MF (denoted by SND-MF_m) which allows multiple links, and the simple SND-MF (denoted by SND-MF_s) where only one link of one type of capacity can be loaded between two routers. Throughout the paper, if no confusion, we will write SND-MF for the two problems SND-MF_m and SND-MF_s.

In what follows we give mixed integer programming formulations for the SND-MF problem. To this end, we first introduce some definitions and notations.

2.3. Definitions and notations

We consider undirected graphs. We denote a graph by G = (V, E)where V is the *node set* and E the *edge set* of G. If $e \in E$ is an edge between two nodes u and v, then we also write e = uv to denote e. We denote also by D = (V, A) the bidirected graph associated with G such that each edge $e = uv \in E$ is replaced by two arcs (u, v) and (v, u), respectively from u to v and from v to u, in the *arc set* A of D. For an edge subset $F \subseteq E$ we denote by $\overrightarrow{F} \subseteq A$ the associated arc subset. For $F \subseteq E$ we let $G \setminus F$ denote the subgraph of G obtained by removing the edges of F and $D \setminus \overrightarrow{F}$ the associated subgraph obtain from D by removing the arcs of \overrightarrow{F} . Throughout the paper we will consider simple graphs.

Let G = (V, E) be a graph. For $W \subseteq V$, we denote by G(W) the subgraph of *G* induced by *W* that is the subgraph having *W* as a node set and all the edges whose both endnodes are in *W*. If $W \subset V$, \overline{W} denotes $V \setminus W$. If *U* and *W* are two node subsets such that $U \cap W = \emptyset$, then we denote by [U, W] the set of edges having one node in *U* and the other in

Fig. 2. Graphs of an IP-over-optical network.

W. If V_1 , ..., V_p is a partition of *V*, we let $\delta_G(V_1, ..., V_p)$ denote the set of edges of *G* between the elements of the partition. If p = 2 and $V_1 = W$, we write $\delta_G(W)$ for $\delta_G(V_1, V_2)$. In this case $\delta_G(W)$ is called a *cut*.

Given a graph G = (V, E), a *path* P in G = (V, E) is an alternate sequence of nodes and edges $(v_1, e_1, v_2, e_2, ..., v_p, e_p, v_{p+1})$ such that $e_i = v_i v_{i+1}$ for i = 1, ..., p and $v_i \neq v_j$ for i = 1, ..., p + 1, j = 1, ..., p + 1. Nodes v_1, v_{p+1} are the endpoints of P and we will say that P goes from v_1 to v_{p+1} or P is between v_1 and v_{p+1} .

Given a vector $x \in IR^E$ and $F \subseteq E$, we let $x(F) = \sum_{e \in F} x(e)$.

Throughout the paper, given an IP-over-optical network, we suppose that to each router of the IP layer corresponds exactly one optical switch. We will represent an IP-over-optical network by two graphs $G^1 = (V^1, E^1)$ and $G^2 = (V^2, E^2)$, that represent the IP and optical networks, respectively. The nodes of G^1 (resp. G^2) correspond to the routers of the IP layer (resp. the optical switches), and the edges represent the possible links between the routers (resp. switches). A vertex $w_i \in V^2$ is associated with a vertex $v_i \in V^1$. For an edge $f \in E^1$, we denote by P_f the path in G^2 corresponding to f. Fig. 2 shows graphs G^1 and G^2 corresponding to the IP-over-optical network of Fig. 1. In G^2 , are indicated two paths P_e and P_f which correspond to the edges e and f of G^1 .

2.4. Formulations

In terms of graphs, the SND-MF problem can be presented as follows.

For an edge e of graph $G^2 = (V^2, E^2)$ corresponding to the optical network, let *** F_e be the set of edges of the IP network that may be affected by a failure of e, that is $F_e = \{f \in E^1 | e \in P_f\}$. We let $\mathcal{F} = \{F_e, e \in E^2\}$. Also we denote by D^1 the directed graph associated with G^1 and $\overrightarrow{\mathcal{F}} = \{\overrightarrow{F_e} \mid F_e \in \mathcal{F}\}$. We denote by K the set of commodities. For each commodity $k \in K$, we know the origin o_k , the destination d_k and the amount ω_k of the demand k.

Let $\mu^1 = \mu = 2.5$ Gbit/s and $\mu^2 = 4\mu = 10$ Gbit/s be the possible capacities. For each $ij \in E^1$, let c_{ij}^l be the cost of installing a capacity μ^l on ij for l = 1, 2. Then, the SND-MF_m problem consists in finding a minimum cost subgraph *H* of G^1 such that for every edge $e \in E^2$, the graph obtained from *H* by removing the edges of F_e has enough capacity to route the commodities of *K* with respect to the capacity of the remaining edges.

In what follows we give two different formulations for the SND-MF problem: the node-arc or conventional formulation and the path or column-generation formulation.

2.4.1. Node-arc formulation

In order to give a node-arc formulation for the SND-MF problem, let us denote by $f_{uv}^{k,e}$ the value of the flow of commodity $k \in K$ on arc $(u, v) \in A^1$, in case of failure of edge $e \in E^2$ (*i.e.*, when the arcs of $\overrightarrow{F_e}$ are removed in D^1). For an edge $uv \in E^1$, let x_{uv}^l be the number of facilities μ^l installed on uv, for l = 1, 2. Set

$$b_k^{\nu} = \begin{cases} -\omega_k & \text{if } \nu = o_k, \\ 0 & \text{if } \nu \neq o_k, \ d_k, \text{for all } \nu \in V^1, \text{ for all } k \in K \\ \omega_k & \text{if } \nu = d_k, \end{cases}$$

Hence the multiple SND-MF problem is equivalent to the following integer programming problem.

Minimize $\sum_{l=1,2} \sum_{uv \in E^1} c_{uv}^l x_{uv}^l$

$$\sum_{u:(u,v)\in A^{1}\setminus\overline{F_{e}}} f_{uv}^{k,e} - \sum_{u:(v,u)\in A^{1}\setminus\overline{F_{e}}} f_{vu}^{k,e} = b_{k}^{v} \text{ for all } v \in V^{1}, \text{ for all } k \in K,$$

for all $e \in E^{2},$ (1)

$$\sum_{v \in K} f_{uv}^{k,e} \leq \mu^1 x_{uv}^1 + \mu^2 x_{uv}^2 \text{ for all } uv \in E^1,$$

for all $e \in E^2,$ (2)

$$\sum_{k \in K} f_{vu}^{k,e} \leq \mu^1 x_{uv}^1 + \mu^2 x_{uv}^2 \text{ for all } uv \in E^1,$$

for all $e \in E^2,$ (3)

 $x_{uv}^l \ge 0$ and integer for all $uv \in E^1$, l = 1, 2, (4)

$$f_{uv}^{k,e}, f_{vu}^{k,e} \ge 0 \text{ for all } uv \in E^1,$$

for all $k \in K$, for all $e \in E^2.$ (5)

Inequalities (1) are called *flow conservation constraints*. Inequalities (2) and (3) express the fact that the sum of the flows of all commodities $k \in K$ on an edge has to be less than or equal to the capacity of this edge. They will be called *capacity constraints*. Inequalities (4) and (5) are called *trivial inequalities*.

By adding the following inequalities

$$x_{uv}^1 + x_{uv}^2 \leqslant 1 \quad \text{for all } uv \in E^1, \tag{6}$$

and by replacing inequalities (4) by

$$x_{uv}^{l} \in \{0, 1\}$$
 for all $uv \in E^{1}, l = 1, 2,$ (7)

we obtain a valid formulation for the simple SND-MF problem.

Inequalities (6) express the fact that only one link can be used between two given nodes. Then we have only one type of capacity on an edge. Constraints (7) are the integrality constraints that express the fact that $x_{uv}^l = 1$ if capacity μ^l , l = 1, 2, is installed on uv and 0 otherwise. Note that the following inequalities

$$f_{uv}^{k,e} + f_{vu}^{k,e} \leqslant \omega_k \quad \text{for all } uv \in E^1, \text{ for all } k \in K, \text{ for all } e \in E^2,$$
(8)

are valid for the SND-MF problem. They are called bound inequalities.

2.4.2. Path formulation

As in the node-arc formulation, for an edge $uv \in E^1$ we denote by x_{uv}^l the number of facilities μ^l installed on uv for l = 1, 2. For an edge $e \in E^2$ and a commodity k we denote by \mathcal{P}_k^e the set of paths from o_k to d_k in the graph $D^1 \setminus \overrightarrow{F_e}^e$ (*i.e.*, when the edge $e \in E^2$ fails). For a path P of \mathcal{P}_k^e , let $y_k^e(P)$ be the amount of flow of commodity k on P in case of failure of e. Let

$$\tau_{uv}(P) = \begin{cases} 1 & \text{if the arc}(u, v) \text{belongs to path } P, \\ 0 & \text{otherwise,} \end{cases}$$

for all $uv \in E^1$. Hence we notice that for all $uv \in E^1$, $k \in K$, and $e \in E^2$,

$$f_{uv}^{k,e} = \sum_{P \in \mathcal{P}_k^e} \tau_{uv}(P) y_k^e(P) = \sum_{P \in \mathcal{P}_k^e \mid (u,v) \in P} y_k^e(P).$$

By substituting the path variables in the node-arc formulation, we obtain the following mixed integer programming formulation which is valid for the multiple SND-MF problem.

Minimize $\sum_{l=1,2} \sum_{uv \in E^1} c_{uv}^l x_{uv}^l$

$$\sum_{P \in \mathcal{P}_k^e} y_k^e(P) = \omega_k \text{ for all } k \in K, \text{ for all } e \in E^2,$$
(9)

$$\sum_{k \in K} \sum_{P \in \mathcal{P}_k^e \mid (u,v) \in P} y_k^e(P) \leq \mu^1 x_{uv}^1 + \mu^2 x_{uv}^2 \text{ for all } uv \in E^1, \text{ for all } e \in E^2,$$
(10)

$$\sum_{k \in K} \sum_{P \in \mathcal{P}_k^e \mid (v,u) \in P} y_k^e(P) \leq \mu^1 x_{uv}^1 + \mu^2 x_{uv}^2 \text{ for all } uv \in E^1, \text{ for all } e \in E^2,$$
(11)

$$y_k^e(P) \ge 0 \begin{cases} \text{for all } e \in E^2, \text{ for all } k \in K, \\ \text{for all } P \in \mathcal{P}_k^e, \end{cases}$$
(12)

$$x_{uv}^l \ge 0$$
 and integer for all $uv \in E^1$, $l = 1, 2.$ (13)

This formulation has a collection of |K| demand constraints (9) that represent the flow of each path P in \mathcal{P}_k^e , $k \in K$ for each failure $e \in E^2$ and $(\sum_{P \in \mathcal{P}_k^e} y_k^e(P)$ represents the amount of flow of commodity k passing through the set of paths from o_k to d_k). This flow has to be equal to the amount ω_k between o_k and d_k . Inequalities (10) and (11) are called *capacity constraints*. The flow through the edge uv has to be less than the capacity of this edge from u to v (constraints (10)) and from v to u(constraints (11)). Inequalities (12) and (13) are the *trivial constraints*.

By adding inequalities (6) and replacing inequalities (13) by inequalities (7), we obtain a valid formulation for the simple SND-MF problem.

The linear relaxation of the node-arc SND-MF formulation contains a large number of constraints and a large number of variables. The linear relaxation of the path formulation, however, contains a moderate number of constraints (for each failure, one for each commodity and one for each arc) and a huge number of variables (one for each path for each commodity for each failure). An appropriate method to solve this second type of formulation would be the column generation approach. In Section 4, we discuss this approach.

3. Valid inequalities and facets

The SND-MF problem can be presented using a single graph G = (V, E) representing the logical layer (*i.e.*, G_2 is omitted) and the edge subsets F_e , $e \in E$, correspond to a family $\mathcal{F} = \{F_1, ..., F_i\}$ of edge subsets of *G*. In what follows we consider this presentation for a polyhedral analysis of the problem.

Throughout the following sections we consider a graph G = (V, E)and the associated digraph D = (V, A) obtained from G by substituting each edge of E by two arcs. We consider also a family $\mathcal{F} = \{F_1, ..., F_i\} \subseteq 2^E, t \ge 2$ of edge subsets of E and the family $\mathcal{F} = \{\overline{F_1}, ..., \overline{F_i}\} \subseteq 2^A$ of arc subsets associated with \mathcal{F} . Let K be a set of demands. For an arc $(u, v) \in A$, a commodity $k \in K$ and $i \in \{1, ..., t\}$, let us denote by $f_{uv}^{k,i}$ the flow of k on (u, v) from u to v when the arcs of $\overline{F_i}$ are removed in D^1 . For $i \in \{1, ..., t\}$, we will denote by $G_i = (V, E_i)$ (resp. $D_i = (V, A_i)$) the subgraph of G (resp. D) obtained by removing the edges of F_i (resp. $\overline{F_i}$). Hence $E_i = E \setminus F_i$ (resp. $A_i = A \setminus \overline{F_i}$).

Now, consider the following inequalities:

$$\sum_{u:(u,v)\in A\setminus\overline{F_i}} f_{uv}^{k,i} - \sum_{u:(v,u)\in A\setminus\overline{F_i}} f_{vu}^{k,i} = b_k^v \text{ for all } v \in V,$$
 for all $k \in K, i = 1, ..., t,$ (14)

$$\sum_{k \in K} f_{uv}^{k,i} \leq \mu x_{uv}^1 + 4\mu x_{uv}^2 \text{ for all } uv \in E, \ i = 1, ..., t,$$
(15)

$$\sum_{k \in K} f_{vu}^{k,i} \leq \mu x_{uv}^1 + 4\mu x_{uv}^2 \text{ for all } uv \in E, \ i = 1, ..., t,$$
(16)

 $x_{uv}^{l} \ge 0 \text{ for all } uv \in E, \ l = 1, 2, \tag{17}$

$$f_{uv}^{k,i}, f_{vu}^{k,i} \ge 0 \quad \text{for all } uv \in E, \\ \text{for all } k \in K, \ i = 1, ..., t,$$

$$(18)$$

$$x_{uv}^1 + x_{uv}^2 \le 1 \text{ for all } uv \in E.$$
(19)

Let SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*) and SND-MF^{*na*}_{*s*}(*G*, \mathcal{F} , *K*) be the polytopes associated with the SND-MF_{*m*} problem and the SND-MF_{*s*} problem *i.e.*,

 $\text{SND-MF}_m^{na}(G, \mathcal{F}, K) = conv\{(x, f) \in \mathcal{D}_m^{na} | x \text{ and } f \text{satisfy}(14) - (18)\},\$

SND-MF^{*na*}_{*s*}(*G*, \mathcal{F} , *K*) = conv{(*x*, *f*) $\in \mathcal{D}_s^{na} | x$ and *f* satisfy(14)–(19)}

with $\mathcal{D}_m^{na} = \{x \in IN^{2|E|}, f \in IR^{2|E| \times |K| \times |\mathcal{F}|}\}$, and $\mathcal{D}_s^{na} = \{x \in \{0, 1\}^{2|E|}, f \in IR^{2|E| \times |K| \times |\mathcal{F}|}\}$. Let \mathcal{P}_k^i be the set of paths between o_k and d_k in the graph $D \setminus \overrightarrow{F_i}$ for

 $i \in \{1, ..., t\}$. Let SND-MF^{*p*}_{*m*}(*G*, \mathcal{F} , *K*) denote the convex hull of the integer solutions of the system

$$\sum_{P \in \mathcal{P}_k^i} y_k^i(P) = \omega_k \text{ for all } k \in K, \ i = 1, ..., t,$$
(20)

$$\sum_{k \in K} \sum_{P \in \mathcal{P}_k^i \mid (u, v) \in P} y_k^i(P) \leq \mu x_{uv}^1 + 4\mu x_{uv}^2 \text{ for all } uv \in E, \ i = 1, \dots, t,$$
(21)

$$\sum_{k \in K} \sum_{P \in \mathcal{P}_k^i \mid (v, u) \in P} y_k^i(P) \leq \mu x_{uv}^1 + 4\mu x_{uv}^2 \text{ for all } uv \in E, \ i = 1, ..., t,$$
(22)

$$x_{uv}^{l} \ge \text{Ofor all } uv \in E, \ l = 1, 2, \tag{23}$$

$$y_k^i(P) \ge 0$$
 for all $k \in K$, $i = 1, ..., t$, (24)

for all $P \in \mathcal{P}_k^i$.

By adding constraints (19) to SND-MF^p_m(G, \mathcal{F}, K), we obtain SND-MF^p_s(G, \mathcal{F}, K).

We can remark that if $G = G^1$ and $\mathcal{F} = \{F_e, e \in E^2\}$, SND-MF^{*p*}_{*m*}(*G*, \mathcal{F} , *K*) (resp. SND-MF^{*s*}_{*s*}(*G*, \mathcal{F} , *K*)) is nothing but the polytope associated with the SND-MF_{*m*} (resp. SND-MF_{*s*}) problem.

If no confusion may arise, we will sometimes write SND- $MF_m(G, \mathcal{F}, K)$ for the two polytopes SND- $MF_m^m(G, \mathcal{F}, K)$ and SND- $MF_m^p(G, \mathcal{F}, K)$. Similarly the polytope SND- $MF_s(G, \mathcal{F}, K)$ will correspond indifferently to the polytopes SND- $MF_s^{n}(G, \mathcal{F}, K)$ and SND- $MF_s^p(G, \mathcal{F}, K)$. We will also sometimes write SND- $MF(G, \mathcal{F}, K)$ for both polytopes SND- $MF_m(G, \mathcal{F}, K)$ and SND- $MF_s(G, \mathcal{F}, K)$.

The following theorem gives the dimension of the polytope SND- $MF_m^{na}(G, \mathcal{F}, K)$.

Lemma 1. $dim(\text{SND-MF}_m^{na}(G, \mathcal{F}, K)) = 2|E| + 2|\mathcal{F}| \times |K| - (|V|-1)|\mathcal{F}| \times |K|.$

Proof. The node-arc formulation of the SND-MF_{*m*} problem contains $2|E| + 2|\mathcal{F}| \times |E| \times |K|$ variables and $(|V|-1)|\mathcal{F}| \times |K|$ nonredundant equality constraints. Hence

 $dim(\text{SND-MF}_m^{na}(G,\mathcal{F},K)) \leq 2|E| + 2|\mathcal{F}| \times |E| \times |K| - (|V|-1)|\mathcal{F}| \times |K|.$

The proof of $dim(SND-MF_m^{rat}(G, \mathcal{F}, K)) \ge 2|E| + 2|\mathcal{F}| \times |E| \times |K| - (|V|-1)|\mathcal{F}| \times |K|$ uses arguments similar to those used in Theorem 6 and we, therefore, omit it.

In what follows, we will show that $dim(\text{SND-MF}_m^{na}(G, \mathcal{F}, K)) \ge 2|E| + 2|\mathcal{F}| \times |E| \times |K| - (|V|-1)|\mathcal{F}| \times |K|$. For this we may suppose that there is at least one path P_i^k between o_k and d_k for all $k \in K$ in G_i for i = 1, ..., t. Otherwise, the problem has a solution. Also suppose that there is an hyperplane

$$a^{1}x + a^{2}x + \lambda f = \alpha \tag{25}$$

which contains SND-MF^{*na*}_m(*G*, *F*, *K*). It suffices to show $a^1 = a^2 = 0$, $\lambda_{uv}^{k,j} = -\lambda_{vu}^{k,j}$ for all $uv \in E$, $k \in K$ and j = 1, ..., t, and $\sum_{k \in K} \sum_{uv \in E} (\lambda_{uv}^{k,j} f_{uv}^{k,j} + \lambda_{vu}^{k,j} f_{vu}^{k,j})$ is a constant for all failure j = 1, ..., t. This implies that any hyperplane containing SND-MF^{*na*}_m(*G*, *F*, *K*) is given by an equation which is a linear combination of Eqs. (14). As the system given by Eqs. (14) is of rank $(|V|-1)|\mathcal{F}| \times |K|$, it will follow that $dim(\text{SND-MF}^{na}_m(G, \mathcal{F}, K)) \ge 2|E| + 2|\mathcal{F}| \times |K| - (|V|-1)|\mathcal{F}| \times |K|$.

To this end, we first construct a feasible solution of SND-MF^{*na*}_{*m*}. We can install on each edge $uv \in E$ a sufficiently large capacity $x_{uv}^2 = c$. We may suppose $c > \sum_{k \in K} \left[\frac{\omega_k}{4\mu} \right]$. And consider the solution (x^1, x^2, f) given by

$$\begin{aligned} x_{uv}^1 &= 0 & \text{ for all } uv \in E, \\ x_{uv}^2 &= c & \text{ for all } uv \in E, \\ f_{uv}^{k,i} &= \omega_k & \text{ for all } k \in K, i = 1, ..., t, uv \\ &\in P_i^k, \text{ and } uv \text{ traversed from } u \text{ to } v \\ &\text{ in } P_i^k, \end{aligned}$$

 $f_{uv}^{k,i} = 0$ otherwise.

Let $u_1v_1 \in E$. Consider the solution $(\widetilde{x}^1, \widetilde{x}^2, \widetilde{f})$ such that

$$\begin{split} &\tilde{x}_{uv_1}^1 = x_{uv_1}^1 + 1, \\ &\tilde{x}_{uv}^1 = x_{uv}^1 \quad \text{for all } uv \in E \setminus \{u_1v_1\}, \\ &\tilde{x}^2 = x^2, \\ &\tilde{f} = f. \end{split}$$

Clearly $(\tilde{x}^1, \tilde{x}^2, \tilde{f})$ is a solution of SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*). As both solutions (x^1, x^2, f) and $(\tilde{x}^1, \tilde{x}^2, \tilde{f})$ satisfy (25), we obtain that $a^1_{u_1v_1} = 0$. As u_1v_1 is an arbitrary edge of *E*, we have that $a^1_{uv} = 0$ for all $uv \in E$. Along the same line, we can show that $a^2_{uv} = 0$ for all $uv \in E$.

same line, we can show that $a_{uv}^2 = 0$ for all $uv \in E$. Next we show that $\lambda_{uv}^{k,j} = -\lambda_{vu}^{k,j}$ for all $uv \in E$, $k \in K$ and j = 1, ..., t. Let $u_1v_1 \in E$. Let $(\overline{x}^1, \overline{x}^2, \overline{f})$ be the solution given by

$$\begin{split} \overline{x}^{1} &= x^{1}, \\ \overline{x}^{2} &= x^{2}, \\ \overline{f}^{k,j}_{u_{1}v_{1}} &= f^{k,j}_{u_{1}v_{1}} + \epsilon, \\ \overline{f}^{k,j}_{v_{1}u_{1}} &= f^{k,j}_{v_{1}u_{1}} + \epsilon, \\ \overline{f}^{k,j}_{uv} &= f^{k,j}_{uv} \quad \text{ for all } uv \in E \setminus \{u_{1}v_{1}\}, k \in K \text{ and } j = 1, ..., t. \end{split}$$

As the capacity of every edge is sufficiently large, we have enough residual capacity to carry more flow. In consequence, $(\bar{x}^1, \bar{x}^2, \bar{f})$ is feasible, and thus satisfies (25). This implies that $\lambda_{u_1v_1}^{k_j} = -\lambda_{v_1u_1}^{k_j}$. As u_1v_1 is arbitrary choosen, it follows that $\lambda_{uv}^{k,j} = -\lambda_{vu}^{k,j}$ for all $uv \in E$, $k \in K$ and j = 1, ..., t.

Now we will show that $\sum_{k \in K} \sum_{uv \in E} (\lambda_{uv}^{k,j} f_{uv}^{k,j} + \lambda_{vu}^{k,j} f_{vu}^{k,j})$ is a constant for all failure j = 1, ..., t, by showing that the sum of the coefficients, corresponding to any circuit in the network, equals zero. Let *C* be a circuit in D = (V, A) Let $k \in K$ and $j \in \{1, ..., t\}$. Consider the solution $(\check{x}^1, \check{x}^2, \check{f})$ such that

$$\begin{split} \ddot{x}^{1} &= x^{1}, \\ \ddot{x}^{2} &= x^{2}, \\ \check{f}_{uv}^{k,j} &= f_{uv}^{k,j} + 1 \quad \text{for all}(u, v) \in C, \\ \check{f}_{uv}^{k,j} &= f_{uv}^{k,j} \quad \text{for all}(u, v) \neg \in C, \\ \check{f}_{uv}^{k,h} &= f_{uv}^{k,h} \quad \text{for all}(u, v) \in A, \text{ for all } h \in \{1, ..., t\} \setminus \{j\}. \end{split}$$

As we have large capacities, $(\check{x}^1, \check{x}^2, \check{f})$ is a solution of SND- $MF_m^{na}(G, \mathcal{F}, K)$. Hence $(\check{x}^1, \check{x}^2, \check{f})$ satisfies (25), and in consequence we obtain that

$$\sum_{(u,v)\in C} (\lambda_{uv}^{k,j} f_{uv}^{k,j} - \lambda_{uv}^{k,j} \check{f}_{uv}^{k,j}) = 0$$

This implies that $\sum_{(u,v)\in C} \lambda_{uv}^{k,j} = 0$. Consequently, we have that $\sum_{k\in K} \sum_{uv\in E} (\lambda_{uv}^{k,j} f_{uv}^{k,j} + \lambda_{vu}^{k,j} f_{vu}^{k,j})$ is a constant, say λ_j for any failure $j \in \{1, ..., t\}$. Thus, it follows that $\sum_{j=1}^{t} \lambda_j = \alpha$, and (25), which can be written as $\lambda f = \alpha$, is nothing but a linear combination of Eq. (14). \Box

In the following, we introduce several classes of valid inequalities. We also give necessary conditions and sufficient conditions for one of these inequalities to be facet defining. We assume that the reader is familiar with polyhedral combinatorics. For more details see (Schrijver, 2003).

3.1. Cut inequalities

For $W \subseteq V$, we denote by $\gamma^+(W) \subseteq K$ (resp. $\gamma^-(W) \subseteq K$) the set of demands which have their origin (resp. destination) in *W* and their destination (resp. origin) in $V \setminus W$. We denote also by $\gamma(W)$ the set $\gamma^+(W) \cup \gamma^-(W)$.

• Design cut inequalities

We first give this theorem which is easily seen to be true.

Theorem 2. Let $F_i \in \mathcal{F}$ be an edge subset of E and $W \subseteq V$, $\emptyset \neq W \neq V$ such that $\gamma(W) \neq \emptyset$. Then the inequality

$$x^{1}(\delta_{G_{i}}(W)) + x^{2}(\delta_{G_{i}}(W)) \ge 1$$
 (26)

is valid for SND-MF(G, \mathcal{F} , K).

Inequalities of type (26) will be called *design cut inequalities*. Theses inequalities express the fact that the graph *G* keeps connectivity between the origin and the destination of each demand after removing the edges of F_i , for all $F_i \in \mathcal{F}$.

• Aggregate capacity inequalities

Given a set of nodes $W \subseteq V$, $\emptyset \neq W \neq V$, let

$$D_W = \left[\max\left\{ \frac{\sum_{k \in \gamma^+(W)} \omega_k}{\mu}, \frac{\sum_{k \in \gamma^-(W)} \omega_k}{\mu} \right\} \right].$$

Let $F_i \in \mathcal{F}$ be an edge subset of E and $W \subseteq V$, $\emptyset \neq W \neq V$. Consider the inequality

$$x^{1}(\delta_{G_{i}}(W)) + 4x^{2}(\delta_{G_{i}}(W)) \ge D_{W}.$$
(27)

We have the following.

Theorem 3. Inequality (27) is valid for SND- $MF(G, \mathcal{F}, K)$.

Proof. The aggregate capacity across $\delta_{G_l}(W)$ must be no less than the demand across the cut from W to $V \setminus W$ and from $V \setminus W$ to W. Thus one should have

$$\mu x^{1}(\delta_{G_{l}}(W)) + 4\mu x^{2}(\delta_{G_{l}}(W)) \ge \max\left\{\sum_{k \in \gamma^{+}(W)} \omega_{k}, \sum_{k \in \gamma^{-}(W)} \omega_{k}\right\}.$$

Dividing by μ and rounding up the right hand side yields (27).

· Capacity demand cut inequalities

Theorem 4. Let $F_i \in \mathcal{F}$ be an edge subset of E and $W \subseteq V$, $\emptyset \neq W \neq V$. Then the inequalities

1.
$$x^{1}(\delta_{G_{l}}(W)) + 2x^{2}(\delta_{G_{l}}(W)) \ge \left\lceil \frac{D_{W}}{2} \right\rceil,$$
 (28)

2.
$$x^{1}(\delta_{G_{l}}(W)) + x^{2}(\delta_{G_{l}}(W)) \ge \left\lceil \frac{D_{W}}{4} \right\rceil,$$
 (29)

3.
$$x^{1}(\delta_{G_{l}}(W)) + 3x^{2}(\delta_{G_{l}}(W)) \ge \left[\frac{3D_{W}}{4}\right],$$
 (30)

4.
$$x^{1}(\delta_{G_{l}}(W)) + 2x^{2}(\delta_{G_{l}}(W)) \ge \begin{cases} \lceil \frac{D_{W}}{2} \rceil + 1 & \text{if } D_{W} \mod 4 = 2, \\ \lceil \frac{D_{W}}{2} \rceil & \text{otherwise,} \end{cases}$$
(31)

are valid for SND-MF(G, \mathcal{F} , K).

Proof.

1. The following inequalities are valid for SND-MF(G, \mathcal{F}, K),

$$\begin{split} x^{1}(\delta_{G_{l}}(W)) + 4x^{2}(\delta_{G_{l}}(W)) \geq D_{W}, \\ x^{1}_{uv} \geq 0 \quad \text{for all } uv \in \delta_{G_{l}}(W). \end{split}$$

By summing these inequalities, we obtain $2x^{l}(\delta_{G_{l}}(W)) + 4x^{2}(\delta_{G_{l}}(W)) \ge D_{W}$. Dividing by 2 and rounding up the right hand side yields inequality (28).

2. By adding the inequalities $x_{uv}^1 \ge 0$ for all $uv \in \delta_{G_l}(W)$ to inequality (28), we get

$$2x^{1}(\delta_{G_{l}}(W)) + 2x^{2}(\delta_{G_{l}}(W)) \ge \left\lceil \frac{D_{W}}{2} \right\rceil$$

Dividing by 2 and rounding up the right hand side yields

$$x^{1}(\delta_{G_{l}}(W)) + x^{2}(\delta_{G_{l}}(W)) \ge \left[\frac{\lceil \frac{D_{W}}{2} \rceil}{2}\right].$$

As $\left[\frac{\lceil \frac{D_{W}}{2} \rceil}{2}\right] = \lceil \frac{D_{W}}{4} \rceil$, we get inequality (29).

3. The following inequalities are valid for SND-MF(G, \mathcal{F}, K),

$$\begin{aligned} x^{1}(\delta_{G_{l}}(W)) &+ 4x^{2}(\delta_{G_{l}}(W)) \geqslant D_{W}, \\ x^{1}(\delta_{G_{l}}(W)) &+ 2x^{2}(\delta_{G_{l}}(W)) \geqslant \left|\frac{D_{W}}{2}\right|. \end{aligned}$$

By summing these inequalities, dividing by 2 and rounding up the right hand side, we obtain

$$\begin{aligned} x^{1}(\delta_{G_{i}}(W)) + 3x^{2}(\delta_{G_{i}}(W)) &\geq \left\lceil \frac{\lceil \frac{3D_{W}}{2} \rceil}{2} \right\rceil. \\ &\text{As}\left\lceil \frac{\left\lceil \frac{3D_{W}}{2} \right\rceil}{2} \right\rceil = \lceil \frac{3D_{W}}{4} \rceil, \text{ we get inequality (30).} \end{aligned}$$

4. By summing inequalities (29) and (30) which are valid by 2 and 3, dividing by 2, and rounding up the right hand side, we obtain the inequality

$$\begin{aligned} x^{1}(\delta_{G_{l}}(W)) + 2x^{2}(\delta_{G_{l}}(W)) &\geq \left[\frac{\lceil \frac{3D_{W}}{4} \rceil + \lceil \frac{D_{W}}{4} \rceil}{2}\right]. \\ As\left[\frac{\lceil \frac{3D_{W}}{4} \rceil + \lceil \frac{D_{W}}{4} \rceil}{2}\right] &= \begin{cases} \lceil \frac{D_{W}}{2} \rceil + 1 & \text{if } D_{W} \mod 4 = 2, \\ \lceil \frac{D_{W}}{2} \rceil & \text{otherwise,} \end{cases} \end{aligned}$$
the result follows

Inequalities (27)–(31) will be called *capacity demand cut inequalities*. One may generate further cut based valid inequalities by combining inequalities of type (27)–(31) and trivial inequalities. However all inequalities obtained this way are redundant with respect to the capacity demand cut inequalities (see (Borne, 2006)).

In the following, we give necessary conditions and sufficient conditions for inequality (27) to be facet defining for SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*). **Theorem 5.** *Inequality* (27) *defines a facet of SND-*MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*) *only if*

1. $G_i(W)$ and $G_i(\overline{W})$ are connected,

- 2. there is no $j \in \{1, ..., t\} \setminus \{i\}$ such that $F_i \cap \delta_G(W) \subset F_j \cap \delta_G(W)$,
- 3. G(W) and $G(\overline{W})$ are \mathcal{F} -connected, if $\delta_G(W) \cap F_i = \emptyset$,

4.
$$D_W > \max\left\{\frac{\sum_{k \in \gamma^+(W)} \omega_k}{\mu}, \frac{\sum_{k \in \gamma^-(W)} \omega_k}{\mu}\right\},$$

5. $D_W \ge 4.$

Proof.

1. Suppose w.l.o.g., that $G_l(W)$ is not connected. Hence there is a partition W_l , W_2 of W such that $\delta_{G_l}(W_l, W_2) = \emptyset$ (see Fig. 3). Thus $\delta_{G_l}(W_1) = \delta_{G_l}(W_1, \overline{W})$ and $\delta_{G_l}(W_2) = \delta_{G_l}(W_2, \overline{W})$. This implies that

Fig. 3. $G_i(W)$ is not connected.

$$\begin{split} & x^{1}(\delta_{G_{l}}(W)) + 4x^{2}(\delta_{G_{l}}(W)) \\ = & x^{1}(\delta_{G_{l}}(W_{1}, \overline{W})) + 4x^{2}(\delta_{G_{l}}(W_{1}, \overline{W})) + x^{1}(\delta_{G_{l}}(W_{2}, \overline{W})) \\ & + 4x^{2}(\delta_{G_{l}}(W_{2}, \overline{W})) \\ = & x^{1}(\delta_{G_{l}}(W_{1})) + 4x^{2}(\delta_{G_{l}}(W_{1})) + x^{1}(\delta_{G_{l}}(W_{2})) + 4x^{2}(\delta_{G_{l}}(W_{2})) \\ \ge & D_{W_{1}} + D_{W_{2}}. \end{split}$$

The last inequality is obtain from the inequalities of type (27) corresponding to W_1 and W_2 . As $D_{W_1} + D_{W_2} \ge D_W$, inequality (27) is redundant with respect to these inequalities and hence (27) cannot be facet defining.

2. Assume the contrary. Let $j \in \{1, ..., t\} \setminus \{i\}$ such that $F_i \cap \delta_G(W) \subset F_j \cap \delta_G(W)$. Then (27) can be obtained as the sum of the following valid constraints.

$$\begin{split} x^{1}(\delta_{G_{j}}(W)) + 4x^{2}(\delta_{G_{j}}(W)) \geq D_{W}, \\ x^{1}_{uv} \geq 0 & \text{for all } uv \in (F_{j} \setminus F_{i}) \cap \delta_{G}(W), \\ 4x^{2}_{uv} \geq 0 & \text{for all } uv \in (F_{i} \setminus F_{i}) \cap \delta_{G}(W). \end{split}$$

Hence it is not facet defining.

3. Suppose $\delta_G(W) \cap F_i = \emptyset$ and w.l.o.g., that G(W) is not \mathcal{F} -connected. Then there is $j \in \{1, ..., t\}$ such that $G_j(W)$ is not connected. If j = i, then by condition (1), (27) cannot define a facet. So suppose $j \neq i$. If $\delta_G(W) \cap F_j \neq \emptyset$, then by condition (2), (27) cannot also define a facet. Thus, suppose that $\delta_G(W) \cap F_j = \emptyset$. Hence, $\delta_G(W) = \delta_{G_i}(W) = \delta_{G_j}(W)$. As $G_j(W)$ is not connected, there is a partition W_1, W_2 of W such that $\delta_{G_j}(W_1, W_2) = \emptyset$. Hence $\delta_{G_i}(W_1) = \delta_{G_i}(W_1, \overline{W})$ and $\delta_{G_i}(W_2) = \delta_{G_i}(W_2, \overline{W})$. This implies that

$$\begin{split} & x^{l}(\delta_{G_{l}}(W)) + 4x^{2}(\delta_{G_{l}}(W)) \\ = & x^{l}(\delta_{G_{j}}(W)) + 4x^{2}(\delta_{G_{j}}(W)) \\ = & x^{l}(\delta_{G_{j}}(W_{1}, \overline{W})) + 4x^{2}(\delta_{G_{j}}(W_{1}, \overline{W})) + x^{l}(\delta_{G_{j}}(W_{2}, \overline{W})) \\ & + 4x^{2}(\delta_{G_{j}}(W_{2}, \overline{W})) \\ = & x^{l}(\delta_{G_{j}}(W_{1})) + 4x^{2}(\delta_{G_{j}}(W_{1})) + x^{l}(\delta_{G_{j}}(W_{2})) + 4x^{2}(\delta_{G_{j}}(W_{2})) \\ \geqslant D_{W_{1}} + D_{W_{2}}. \end{split}$$

Since $D_{W_1} + D_{W_2} \ge D_W$, as before, inequality (27) cannot then define a facet.

- 4. If $D_W = \max\left\{\frac{\sum_{k \in \gamma^+(W)} \omega_k}{\mu}, \frac{\sum_{k \in \gamma^-(W)} \omega_k}{\mu}\right\}$, then constraint (27) is redundant with respect to constraints (14)–(16), and hence does not define a facet.
- If D_W < 4, then for every solution of SND-MF^{na}_n that satisfies (27) with equality we have x²(e) = 0 for all e ∈ δ_G(W).
 - The idea of the proof is to find two different equations satisfied by all the solutions of the face induced by (27) and which are linearly independent (non redundant) with respect to flow Eqs. (14). This implies that the dimension of the face is less than or equal to dim (SND-MF^{ma}_m(G, \mathcal{F}, K))-2, and cannot then be a facet. Note that by Lemma 1, dim(SND-MF^{ma}_m(G, \mathcal{F}, K)) is equal to the number of edges minus the rank of system (14).

If $|\delta_{G_i}(W)| \ge 2$, then there are two edges $e_1, e_2 \in \delta_{G_i}(W)$ such that

 $x^2(e_1) = x^2(e_2) = 0$ in every solution satisfying (27) with equality. If, say, $\delta_{G_i}(W) = \{e\}$, then in every solution satisfying (27) with equality, one should have $x^{1}(e) = D_{W}$ and $x^{2}(e) = 0$. In both cases, the two equations are non redundant with respect to (14), and hence (27) cannot define a facet. \Box

As in Borne et al. (2006), a subgraph H = (W, F) of G = (V, E) is said to be \mathcal{F} -connected with respect to $\mathcal{F} = \{F_1, ..., F_t\}$ if for all $i \in \{1, ..., t\}$, the graph $H \setminus F_i$ is connected.

Theorem 6. Inequality (27) defines a facet of SND-MF^{*na*}_{*m*}(G, \mathcal{F}, K) if

1. condition (1), (2), (3), (4) of Theorem 5 are satisfied, 2. G(W) and $G(\overline{W})$ are \mathcal{F} -connected.

Proof. See Appendix.

In Magnanti et al. (1995) introduce cutset inequalities valid for the Two-Facility Capacitated Network Loading Problem (TFLP). These can be easily extended to the $SND-MF_m$ and the $SND-MF_s$ problems. The extended ones are special cases of the capacity demand cut inequalities.

Corollary 7. Let $F_i \in \mathcal{F}$ be an edge subset of $E, W \subseteq V, \emptyset \neq W \neq V$, and let $r_W = \begin{cases} 4 \text{ if } D_W \mod 4 = 0, \\ D_W \mod 4 \text{ otherwise.} \end{cases}$

Then the inequality

$$\sum_{e \in \delta_{G_i}(W)} \left(x_e^1 + r_W x_e^2 \right) \ge r_W \left[\frac{D_W}{4} \right]$$
(32)

is valid for both SND-MF_m(G, \mathcal{F} , K) and SND-MF_s(G, \mathcal{F} , K).

Proof.

- If $r_W = 1$, inequality (32) is nothing but inequality (29).
- If $r_W = 2$, as $2\left[\frac{D_W}{4}\right] = \left[\frac{D_W}{2}\right] + 1$, inequality (32) is nothing but inequality (31).
- If $r_W = 3$, as $3\left\lfloor \frac{D_W}{4} \right\rfloor = \left\lfloor \frac{3D_W}{4} \right\rfloor$, inequality (32) is nothing but inequality
- If $r_W = 4$, as $4\left[\frac{D_W}{4}\right] = D_W$, inequality (32) is nothing but inequality (27). □

3.2. Saturation inequalities

In this section we introduce a further class of inequalities which are only valid for the polytope SND-MF_s(G, \mathcal{F}, K). These inequalities are also induced by cuts in the graph G_i . In these inequalities only the x^2 variables, associated with the links with big capacity ($4\mu = 10$ Gbits), are involved. In fact, the idea behind these inequalities is that if the demand cannot be routed on the links of a cut with small capacity ($\mu = 2.5$ Gbits), then at least one big capacity must be installed on one of the links of the cut.

Theorem 8. Let $F_i \in \mathcal{F}$ and $W \subseteq V, \emptyset \neq W \neq V$. Then inequality

$$x^{2}(\delta_{G_{l}}(W)) \geq \left| \frac{\max\left\{\sum_{k \in \gamma^{+}(W)} \omega_{k}, \sum_{k \in \gamma^{-}(W)} \omega_{k}\right\} - |\delta_{G_{l}}(W)| \times \mu}{3\mu} \right|$$
(33)

is valid for $SND-MF_s(G, \mathcal{F}, K)$.

Proof. By (6) and (27), the following inequalities are valid for SND- $MF_s(G, \mathcal{F}, K)$

$$\mu x^{1}(\delta_{G_{l}}(W)) + 4\mu x^{2}(\delta_{G_{l}}(W)) \ge \max\left\{\sum_{k \in \gamma^{+}(W)} \omega_{k}, \sum_{k \in \gamma^{-}(W)} \omega_{k}\right\},$$
(34)

$$-\mu x^{1}(e) - \mu x^{2}(e) \ge -\mu, \text{ for all } e \in \delta_{G_{l}}(W).$$
(35)

By summing these inequalities, dividing by 3μ and rounding up the

Fig. 4. A cut-cycle configuration.

right hand side, we obtain inequality (33).

In the two following sections we present further classes of valid inequalities which are extensions of valid inequalities introduced in Borne et al. (2006) for the problem without capacities.

3.3. Cut-cycle inequalities

Let $W \subset V$ and $T_1 = \{e_1, ..., e_s\}, s \ge 3$, be an edge subset of $\delta_G(W)$. Let $1 \leq q < s$ be an integer. Suppose that for every i = 1, ..., s, there is $j_i \in \{1, ...t\}$ such that $F_{j_i} \cap T_1 = \{e_i, ..., e_{i+q-1}\}$ (the indices are modulo s). Let $T_2 = \delta_G(W) \setminus (T_1 \cup (\bigcap_{i=1,\dots,s} F_{j_i}))$. Such a configuration (W, T_1, T_2) will be called a cut-cycle configuration (see Fig. 4).

Theorem 9. Let (W, T_1, T_2) be a cut-cycle configuration such that $\gamma(W) \neq \emptyset$. For $e \in \delta_G(W)$, let $r_e = |\{i \in \{1, ..., s\}$ such that $e \in \delta_G(W) \setminus F_i\}|$ and *r* be the smallest integer such that $r(s-q) \ge \max_{e \in T_2} \{r_e\}$. Then inequality

$$\sum_{l=1,2} \left(x^l(T_1) + rx^l(T_2) \right) \ge \left[\frac{s}{s-q} \right]$$
(36)

is valid for SND-MF(G, \mathcal{F}, K).

Proof. The following inequalities are valid for SND-MF(G, \mathcal{F}, K),

$$\sum_{l=1,2} x^{l} (\delta_{G_{j_{l}}}(W)) \ge 1 \quad \text{for} i = 1, ..., s,$$
$$(r(s-q)-r_{e})x^{l}(e) \ge 0 \quad \text{for all } e \in T_{2}, \ l = 1, 2.$$

By summing these inequalities, we obtain

$$\sum_{l=1,2} ((s-q)x^{l}(T_{1}) + r(s-q)x^{l}(T_{2})) \ge s.$$

By dividing by s-q and rounding up the right hand side we get inequality (36).

Inequalities (36) will be called *design cut-cycle inequalities*.

Theorem 10. Let (W, T_1, T_2) be a cut-cycle configuration such that $\gamma(W) \neq \emptyset$. For $e \in \delta_G(W)$, let $r_e = |\{i \in \{1, ..., s\} | e \in \delta_G(W) \setminus F_i\}|$, and r be the smallest integer such that $r(s-q) \ge \max_{e \in T_2} \{r_e\}$. Let $r_W = \begin{cases} 4 \text{ if } D_W \mod 4 = 0\\ D_W \mod 4 \text{ otherwise.} \end{cases}$ Then the inequality

$$x^{1}(T_{1}) + r_{W}x^{2}(T_{1}) + rx^{1}(T_{2}) + r \times r_{W}x^{2}(T_{2}) \ge \left[\frac{s}{s-q} \times r_{W}\left[\frac{D_{W}}{4}\right]\right]$$
(37)

is valid for $SND-MF(G, \mathcal{F}, K)$.

Proof. By Theorem 7, the following inequalities are valid for SND-MF $(G, \mathcal{F}, K),$

$$\sum_{e \in \delta_{G_{j_i}^{(W)}}} (x_e^1 + r_W x_e^2) \ge r_W \left\lceil \frac{D_W}{4} \right\rceil \quad \text{for } i = 1, ..., s$$

Also consider the following inequalities which are also valid for SND- $MF(G, \mathcal{F}, K).$

S. Borne et al.

 $(r(s-q)-r_e)x^1(e) \ge 0$ for all $e \in T_2$, $(r(s-q)-r_e)r_wx^2(e) \ge 0$ for all $e \in T_2$.

By summing these inequalities we obtain

$$\begin{split} &\sum_{e \in T_1} \left[(s - q) x_e^1 + (s - q) r_W x_e^2 \right] + \sum_{e \in T_2} \left[r(s - q) x_e^1 + r(s - q) r_W x_e^2 \right] \ge \\ &s \times r_W \left[\frac{D_W}{4} \right]. \end{split}$$

By dividing this inequality by s-q and rounding up the right hand side we get inequality (37). \Box

Inequalities (37) will be called *capacity cut-cycle inequalities*. We can remark that if $r_W = 1$ and $\left\lceil \frac{D_W}{4} \right\rceil = 1$ we then obtain the design cut-cycle inequalities (36).

3.4. Star-partition inequalities

Let G = (V, E) be a graph and $\mathcal{F} = \{F_1, ..., F_l\}$, with $t \ge 2$, a family of edge subsets of *E*. Let $V_0, V_1, ..., V_p$ be a partition of *V* with *p* odd. Suppose that for every i = 1, ..., p, there is $j_i \in \{1, ..., t\}$ such that $F_{j_i} \cap [V_i, V_0] \ne \emptyset$. Let $\Lambda = \{e \in E \mid e \in [V_k, V_l] \cap F_{j_k} \cap F_{j_l}$, for some $k, l \in \{1, ..., p\}$. Let $F = \bigcup_{i=1}^p (F_{j_i} \cap [V_i, V_0]) \cup \Lambda$. Such a configuration will be called a *star-partition configuration* (see Fig. 5).

Theorem 11. Let $(V_0, V_1, ..., V_p, F)$ be a star-partition configuration with p odd such that $\gamma(W) \neq \emptyset$. Then the inequality

$$\sum_{l=1,2} x^{l}(\delta_{G}(V_{0}, ..., V_{p}) \setminus F) \ge \left\lceil \frac{p}{2} \right\rceil$$
(38)

is valid for SND-MF(G, \mathcal{F} , K).

Proof. It is clear that the following inequalities are valid for SND-MF (G, \mathcal{F}, K) .

$$\begin{split} \sum_{l=1,2} x^l (\delta_{G \setminus F_{j_l}}(V_l)) &\ge 1 \quad \text{for } i = 1, \, ..., \, p, \\ x^l(e) &\ge 0 \quad \text{for all } e \in \delta(V_0) \setminus F, \, l = 1, \, 2, \\ x^l(e) &\ge 0 \quad \text{for all } e \in (\delta_G(V_k, \, V_m) \cap F_{j_k}) \setminus F_{j_m}, \\ k &= 1, \, ..., \, p, \, m = 1, \, ..., \, p, \, k \neq m, \quad l = 1, \, 2. \end{split}$$

By summing these inequalities, we obtain inequality

 $2\sum_{l=1,2} x^l(\delta(V_0,\,...,\,V_p)\backslash F) \ge p.$

By dividing by 2 and rounding up the right hand side, we obtain inequality (38). \Box

Inequalities (38) will be called design star-partition inequalities.

Fig. 5. A star-partition configuration.

$$\begin{aligned} \text{Theorem 12. Let } (V_0, V_1, ..., V_p, F) \text{ be a star-partition configuration.Let} \\ r_{V_i} = \begin{cases} 4 \text{ if } D_{V_i} \mod 4 = 0, \\ D_{V_i} \mod 4 \text{ otherwise}, \text{ for } i = 1, ..., p. \text{ Set } r_e = \sum_{e \in \delta_G \setminus F_{I_i}(V_i)}^{i=1, ..., p:} r_{V_i} \text{ and} \\ \lambda_e = \begin{cases} r_e & \text{ if } r_e \text{ is even}, \\ r_e + 1 & \text{ otherwise}, \end{cases} e \in \delta_G(V_0, ..., V_p) \setminus F. \text{ Then inequality} \\ \sum_{e \in \delta_G(V_0, ..., V_p) \setminus F} \left(x_e^1 + \frac{\lambda_e}{2} x_e^2 \right) \ge \left[\frac{\sum_{i=1}^p r_{V_i} \left[\frac{D_{V_i}}{4} \right]}{2} \right] \end{aligned} \end{aligned}$$

$$(39)$$

is valid for SND-MF(G, \mathcal{F} , K).

Proof. The following inequalities are valid for SND-MF(G, \mathcal{F} , K).

$$\sum_{e \in \delta_G \setminus F_{j_i}(V_i)} (x_e^1 + r_{V_i} x_e^2) \ge r_{V_i} \left\lfloor \frac{D_{V_i}}{4} \right\rfloor \quad \text{for } i = 1, ..., p,$$

- $x_e^1 \ge 0$ for all $e \in \delta_G(V_0, ..., V_p) \setminus F$,
- $x_e^2 \ge 0$ for i = 1, ..., p, for all $e \in \delta_G(V_i, V_0) \setminus F$, such that r_{V_i} is odd,

for all
$$e \in \delta_G(V_k, V_m) \setminus (F_{i_k} \cap F_{i_m})$$
, such that r_e is odd,

$$\begin{aligned} & x_e \ge 0 & k = 1, ..., p, \ m = 1, ..., p, \ k \ne m, \\ & \text{for all } e \in (\delta_G(V_k, V_m) \cap F_{j_k}) \setminus F_{j_m}, \ k = 1, ..., p, \\ & x_e^1 \ge 0 \end{aligned}$$

$$x_e^2 \ge 0 \qquad \qquad \text{for all } e \in (\delta_G(V_k, V_m) \cap F_{j_k}) \setminus F_{j_m}, \text{ such that } r_{V_m} \text{ is odd,} \\ k = 1, \dots, p, \ m = 1, \dots, p, \ k \neq m.$$

By summing these inequalities we get
$$\sum_{e \in \delta_G(V_0, \dots, V_p) \setminus F} (2x_e^1 + \lambda_e x_e^2) \ge \sum_{i=1}^s r_{V_i} \left[\frac{D_{V_i}}{4} \right].$$

As λ_e 's, $e \in \delta_G(V_0, ..., V_p) \setminus F$ are all even, by dividing this inequality by 2 and rounding up the right hand side we get the inequality

$$\sum_{e \in \delta_G(V_0, \dots, V_p) \setminus F} \left(x_e^1 + \frac{\lambda_e}{2} x_e^2 \right) \ge \left| \frac{\sum_{i=1}^s r_{V_i} \left[\frac{D_{V_i}}{4} \right]}{2} \right|. \qquad \Box$$

Inequalities (39) are called capacity star-partition inequalities.

3.5. Other valid inequalities

The Arc Residual Capacity inequalities have been introduced in Magnanti et al. (1993) for the Network Loading Problem and used for the Two-Facility capacitated network loading Problem (Magnanti et al., 1995). In the following we extend these inequalities for our problem.

Theorem 13. Let $L \subseteq K$. Set

$$Q_L = \frac{\sum_{k \in L} \omega_k}{\mu}, \ \sigma_L = \left\lceil \frac{Q_L}{4} \right\rceil \text{ and } s_L = \begin{cases} 4 \text{ if } Q_L \mod 4 = 0, \\ Q_L \mod 4 \text{ otherwise} \end{cases}$$

Then we have $Q_L = 4(\sigma_L - 1) + s_L$. Let $u, v \in V^1$ and $e \in E^2$, then the inequality

$$\frac{1}{\mu} \sum_{k \in L} (f_{uv}^{k,e} + f_{vu}^{k,e}) - 2x_{uv}^1 - s_L \times 2x_{uv}^2 \le (\sigma_L - 1)(4 - s_L)$$
(40)

is valid for SND-MF(G, \mathcal{F} , K).

Proof. Inequality (40) can be written as

$$\frac{1}{\mu} \sum_{k \in L} (f_{uv}^{k,e} + f_{vu}^{k,e}) \leq Q_L - s_L (\sigma_L - 2x_{uv}^2) + 2x_{uv}^1$$

for $L \subseteq K$, $u, v \in V^1$ and $e \in E^2$ because $(\sigma_L - 1)(4 - s_L) = Q_L - \sigma_L s_L$.

• If
$$2x_{uv}^2 \ge \sigma_L$$
 then $Q_L - s_L(\sigma_L - 2x_{uv}^2) + 2x_{uv}^1 \ge Q_L$.

We know that inequalities (8) are valid for the problem. By summing these inequalities, we obtain

$$\sum_{k\in L} (f_{uv}^{k,e} + f_{vu}^{k,e}) \leq \sum_{k\in L} \omega_k.$$

Then

 $\frac{1}{\mu}\sum_{k\in L} (f_{uv}^{k,e} + f_{vu}^{k,e}) \leq Q_L,$

which implies that inequality (40) is valid. • If $2x_{uv}^2 \leq \sigma_L - 1$, then

$$\begin{aligned} Q_L - s_L(\sigma_L - 2x_{uv}^2) + 2x_{uv}^1 &= 4(\sigma_L - 1) + s_L - s_L(\sigma_L - 2x_{uv}^2) + 2x_{uv}^1 \\ &= 4(\sigma_L - 1) + s_L(2x_{uv}^2 - (\sigma_L - 1)) + 2x_{uv}^1. \end{aligned}$$

Let $s_L = 4-t$ with $0 \le t < 4$, we obtain.

$$\begin{aligned} Q_L - s_L(\sigma_L - 2x_{uv}^2) + 2x_{uv}^1 &= 4(\sigma_L - 1) + (4 - t)(2x_{uv}^2 - (\sigma_L - 1)) + 2x_{uv}^1 \\ &= 8x_{uv}^2 + 2x_{uv}^1 + t(-2x_{uv}^2 + (\sigma_L - 1)). \end{aligned}$$

Then

 $\begin{aligned} Q_{L} - s_{L}(\sigma_{L} - 2x_{uv}^{2}) &+ 2x_{uv}^{1} \geqslant 8x_{uv}^{2} + 2x_{uv}^{1}, \end{aligned} \tag{41} \\ \text{because } t \geqslant 0 \text{ and } 2x_{uv}^{2} \leqslant \sigma_{L} - 1. \text{ As} \\ \sum_{k \in K} f_{uv}^{k,e} &\leq \mu x_{uv}^{1} + 4\mu x_{uv}^{2} \text{ and } \sum_{k \in K} f_{vu}^{k,e} \leqslant \mu x_{uv}^{1} + 4\mu x_{uv}^{2}, \end{aligned} \\ \text{then } \frac{1}{\mu} \sum_{k \in K} (f_{uv}^{k,e} + f_{vu}^{k,e}) \leqslant 2x_{uv}^{1} + 8x_{uv}^{2}, \text{ and hence} \\ \frac{1}{\mu} \sum_{k \in L} (f_{uv}^{k,e} + f_{vu}^{k,e}) \leqslant 2x_{uv}^{1} + 8x_{uv}^{2}. \end{aligned}$

By (41) and (42), it follows that inequality (40) is valid. \Box

4. Branch-and-Cut and Branch-and-Cut-and-Price algorithms

In this section, we describe four algorithms for the SND-MF problem. We consider the two variants of the problem (simple and multiple) and for each variant we propose a Branch-and-Cut algorithm based on the node-arc formulation and a Branch-and-Cut-and-Price algorithm based on the path formulation. Our aim is to address the algorithmic applications of the previous results.

We now describe the framework of our algorithms. For the Branchand-Cut algorithms based on the node-arc formulation, we start the optimization with the linear relaxations of the considered formulations. The optimal solutions (x^1, x^2, f) of these relaxations are feasible for the SND-MF problems if x^1 and x^2 are integral.

For the Branch-and-Cut-and-Price algorithms, we start the optimization by solving the linear relaxation of the path formulations. For this we use a standard column generation algorithm.

4.1. Column generation

This approach has been extensively used for modeling and solving large scale multicommodity flow problems (Ahuja, Magnanti, & Orlin, 1993; Barnhart, Johnson, Nemhauser, Savelsbergh, & Vance, 1998; Lübbecke & Desrosiers, 2004). The general idea of column generation is to solve a restricted linear program (called the *master problem*) with a small number of variables (columns) in order to determine an optimal solution for the master problem. In fact a limited number of variables may induce an optimal basic solution for the master problem. So the column generation algorithm solves the linear relaxation of the master problem by solving the linear relaxations of several restricted master problems. After determining the solution of the linear relaxation of a restricted master problem, we use the *pricing problem* which consists in finding whether there are any columns not yet in the restricted master problem with negative reduced cost. If none can be found, then the current solution of the restricted master problem is optimal for the linear relaxation of the master problem. However, if one or more such columns do exist, then they are added to the restricted master problem and the process is repeated until no variable with negative reduced cost exists. This approach can be combined with row generation to obtain a very strong method to solve the linear relaxations (see Barnhart, Hane, & Vance, 2000).

To start the column generation scheme, an initial restricted master problem has to be provided. This initial problem must have a feasible solution to ensure that correct information is passed to the pricing problem.

For the version of the SND-MF problem with multiple edges (SND- MF_m problem), finding an initial feasible solution is very easy. Indeed we look for shortest paths between the origin-destinations of all commodities. These paths are then used to carry the flow for each commodity. As we can install as much capacity as we want, this multicommodity flow is feasible.

For the SND-MF_s problem, we consider an auxiliary master problem where $x_{uv}^{1} = 0$ and $x_{uv}^{2} = 1$ for all edge $uv \in E^{1}$ (that is to say, we fix the capacity of each edge to the highest possible value, *i.e.*, $4\mu = \mu_{2} = 10$ Gbits), and the objective is to minimize the maximum excess of flow on any edge (amount of flow exceeding the capacity), denoted ε . If the optimal solution for this linear program is such that $\varepsilon > 0$, we conclude that the SND-MF_s problem has no solution. On the other hand, if $\varepsilon = 0$, then the set of variables used in the column generation permits to have an initial feasible solution for the restricted master problem.

For any restricted master problem, let γ_k^e , $\vartheta_{(u,v)}^e$ and $\vartheta_{(v,u)}^e$ be the dual variables associated with constraints (9)–(11), respectively. The reduced cost associated with the variable of a path $P \in \mathcal{P}_k^e$ is $R_P^{k,e} = \sum_{(u,v) \in P} \vartheta_{(u,v)}^e - \gamma_k^e$. The pricing problem can then be reduced to the resolution of several shortest path problems with non-negative costs. Indeed the pricing problem consist in finding for each commodity $k \in K$ and each edge $e \in E^2$, a path P in \mathcal{P}_k^e such that $R_P^{k,e} = \min_{P' \in \mathcal{P}_k^e} R_{P'}^{k,e}$ and $R_P^{k,e} < 0$. Therefore, we can identify columns which have to be added to the restricted master problem by solving one shortest path problem for each commodity $k \in K$ and each edge $e \in E^2$ in the graph with arc costs equal to $\vartheta_{(u,v)}^e$ for each $(u, v) \in A^1 \setminus \overline{F_e}$. If one or more paths have nonpositive reduced cost, then they are added in the restricted master problem has been solved to optimality.

Combining column and row generation can yield a very strong linear relaxation. In the next section, we describe some valid inequalities. These will be used as cutting planes in our Branch-and-Cut-and-Price algorithm for the two variants of the problem. We introduce some inequalities which are valid for the problem with or without multiple edges.

A solution (x^1, x^2, f) obtained after a column generation phase is feasible for the SND-MF problems only if x^1 and x^2 are integral. Usually, such a solution is not feasible, and thus, in each iteration of the Branchand-Cut and the Branch-and-Cut-and-Price algorithms, it is necessary to generate further inequalities that are valid for the SND-MF problem but violated by the current solution (x^1, x^2, f) . For this, one has to solve the so-called *separation problem*.

4.2. Separation algorithms

Given a class of inequalities, the separation problem associated with these inequalities consists in deciding whether a solution (x^1, x^2, f) satisfies the inequalities, and if not, in finding an inequality that is violated by (x^1, x^2, f) . An algorithm which solves this problem is called a *separation algorithm*. The inequalities given above are all valid for the four polytopes SND-MF^m_n, SND-MFⁿ_m, SND-MF^{na}_s and SND-MF^p_s except the saturation inequalities which are valid only for the simple version of the problem. Hence these inequalities are used in our algorithms. The separation is performed in the following order:

1. arc residual capacity constraints (40) (for the Branch-and-Cut

algorithms only),

- 2. design cut constraints (26) and capacity demand cut constraints (27)–(31),
- 3. saturation constraints (33) (for SND-MF_s only),
- 4. design cut-cycle constraints (36),
- 5. capacity cut-cycle constraints (37),
- 6. design star-partition constraints (38),
- 7. capacity star-partition constraints (39).

We remark that all the inequalities are global (*i.e.*, valid in all the Branch-and-Cut tree and the Branch-and-Cut-and-Price tree) and several constraints may be added at each iteration. Moreover, we go to the next class of inequalities only if the separation of the previous class of inequalities does not generate any violated inequality. Our strategy is to try to detect violated constraints at each node of the Branch-and-Cut tree in order to obtain the best possible lower bound and thus limit the number of generated nodes. Generated inequalities are added by sets of at most 200 inequalities at a time.

Now we describe the separation procedures used in our algorithms. All our separation algorithms are applied on $G_{(\overline{x}^1, \overline{x}^2)} = (V, E_{(\overline{x}^1, \overline{x}^2)})$ where $(\overline{x}^1, \overline{x}^2)$ is the restriction on x^1 and x^2 of the current LP solution, and $E_{(\overline{x}^1, \overline{x}^2)}$ contains all the edges uv of E such that $\overline{x}_{uv}^1 + \overline{x}_{uv}^2 \neq 0$.

To separate the design cut inequalities (26) and the capacity demand cut inequalities (27)–(31), we have developed a fast heuristic. We first check whether a degree cut $\delta_{G_{(\chi^1,\chi^2)}}(v), v \in V$, is violated. Then we start contracting edges uv with high value $\mu \overline{x}_{uv}^1 + 4\mu \overline{x}_{uv}^2 - \sum_{k \in \gamma([u]) \cup \gamma([v])} \omega_k$ until we get a graph on two nodes. In each iteration we check if the cut associated with the node arising from the contraction, induces a violated constraint of type (27), (29), (30) or (31). This runs in O(mlogm) time where *m* is the number of edges of *G*.

When this heuristic does not find any violated inequalities, we compute the so-called Gomory-Hu tree (Gomory & Hu, 1961) on the graph $G_{(x^1,x^2)}$ with the weight $\overline{x}_{uv}^1 + \overline{x}_{uv}^2$ for each edge uv. This tree has the property that for all pairs of nodes $s, t \in V$, the minimum (s, t)-cut in the tree is also a minimum (s, t)-cut in $G_{(x^1,x^2)}$. Actually, we use the algorithm developed by Gusfield (1990) which requires |V|-1 maximum flow computations. The maximum flow computations are handled by the efficient Goldberg and Tarjan algorithm (Goldberg & Tarjan, 1988) that runs in $O(mn \log \frac{n^2}{m})$. Here n is the number of nodes of G. Then we calculate the right hand side for all the cuts in the Gomory-Hu tree and check if the found constraints are violated.

During the separation of the saturation constraints (33), we consider the cuts $\delta_{G_{(\chi^1,\chi^2)}}(v)$, $v \in V$. We test if these inequalities are violated and if so we add them to the program. We don't consider the other cuts of the graph $G_{(\chi^1,\chi^2)}$ induced by at least two nodes which seem almost never be violated.

Now we turn our attention to the separation of the cut-cycle inequalities (36) and (37). For more efficiency, we have used these constraints only when q = 1. In fact we remarked that the design cut-cycle inequalities and the capacity cut-cycle inequalities which are violated are usually of this type.

To separate the design cut-cycle constraints with q = 1, we compute the Gomory-Hu tree of the graph $G_{(\overline{x}^1, \overline{x}^2)}$ with the weight for each edge uv equal to the sum $\overline{x}_{uv}^1 + \overline{x}_{uv}^2$. Then for each cut given by the Gomory-Hu tree, with value less than 2, we test if the cut intersects at least one demand. If this is the case, then it yields a design cut-cycle inequality (36) violated by $(\overline{x}^1, \overline{x}^2)$. Then sets T_1 and T_2 are determined so that T_1 is maximal, using the following greedy procedure (Algorithm 1). Since the Gomory-Hu algorithm runs with a large complexity, in order to accelerate our separation for the cut-cycle inequalities, we first consider the degree cuts $\delta_{G_{(\overline{x}^1,\overline{x}^2)}}(v), v \in V$. The computation of the Gomory-Hu tree is considered only if no cuts of this type of value less than 2 are found. Thus the separation of the cut-cycle inequalities runs in $O(mn \log \frac{n^2}{m})$ time. Algorithm 1. Algorithm 1

$$\begin{split} T_1 &\leftarrow \varnothing; T_2 \leftarrow \varnothing; \overline{\mathcal{F}} \leftarrow \varnothing; \\ \text{for } i = 1 \text{ to } m \text{ do} \\ & \text{ if } f_i \in F_{j_0} \text{ for some } j_0 \in \{1, \, ..., \, t\} \text{ and } f_i \neg \in F_j \text{ for all } F_j \in \overline{\mathcal{F}} \\ \text{ then } \\ & T_1 \leftarrow T_1 \cup \{f_i\}; \\ & \overline{\mathcal{F}} \leftarrow \overline{\mathcal{F}} \cup \{F_{j_0}\}; \\ & \text{ else } \\ & T_2 \leftarrow T_2 \cup \{f_i\}; \\ & \text{ end if } \\ & \text{ end for } \\ & \text{ for all } f_i \in T_2 \\ & \text{ if } f_i \in F_j \text{ for all } F_j \in \overline{\mathcal{F}} \text{ then } \\ & T_2 \leftarrow T_2 \setminus \{f_i\}; \\ & \text{ end if } \\ & \text{ end for } \\ \end{array}$$

For the separation of the capacity cut-cycle constraints, we first consider the degree cuts $\delta_{G_{(\chi^1,\chi^2)}}(v)$, $v \in V$. We calculate the right hand side. If the associated constraint is violated, we then determine the sets T_1 and T_2 using Algorithm 1. Then we start contracting edges until we get a graph on two nodes. In each iteration we contract an edge uv with the biggest value for $\mu \overline{x}_{uv}^1 + 4\mu \overline{x}_{uv}^2 - \sum_{k \in \gamma(\{u\}) \cup \gamma(\{v\})} \omega_k$ and check whether the new node obtained by contraction together with T_1 and T_2 induces a violated capacity cut-cycle inequality. This heuristic runs in $O(m \log m)$ time.

We now discuss our separation routine for the star-partition inequalities (38) and (39). We use a linear greedy heuristic which consists in determining fractional cycles in the supporting graph, satisfying some conditions. These cycles have to be odd, in order to have a chance to find a violated design star-partition inequality. Thus, for each detected cycle $(v_1, ..., v_p)$ we try to find edge subsets $F_{j_i}, j_i \in \{1, ..., t\}, i = 1, ..., p$ among the edges of $[v_i, V \setminus \{v_1, ..., v_p\}]$ in such a way that either the design star-partition inequality or the capacity star-partition induced by $V \setminus \{v_1, ..., v_p\}, \{v_1\}, ..., \{v_p\}, \text{ and } F_{j_i}, i = 1, ..., p$ is violated by $(\overline{x}^1, \overline{x}^2)$.

To store the generated inequalities, we created a pool whose size increases dynamically. All the generated inequalities are put in the pool and are dynamic, *i.e.*, they are removed from the current LP when they are not active. We first separate inequalities from the pool. If all the inequalities in the pool are satisfied by the current LP-solution, then we separate the classes of inequalities in the order given above.

In the following section, we give some computational results obtained with the algorithms presented above for random instances and for real instances provided by Orange Labs.

5. Computational results

The Branch-and-Cut and Branch-and-Cut-and-Price algorithms described in the previous section have been implemented in C + +, using ABACUS¹ (A Branch-And-CUt System) 2.4 alpha (Elf, Gutwenger, Jünger, & Rinaldi, 2001; Thienel et al., 1995) to manage the Branch-and-Cut tree and Cplex 9.0² as LP-solver. It was tested on a Pentium IV 2,4 GHz with 1 Gb RAM, running under Linux. We fixed the maximum CPU time to 5 h.

Results are presented here for instances coming from real applications and instances obtained from problems of the TSP Library (Reinelt, 1991) by randomly generating the node set, the edge sets F_e and the set

of demands *K*. For all the instances, the graph G^1 , representing the IP network, is considered complete.

These instances were generated with 6, 8 and 10 nodes, $|\mathcal{F}| = 10$, 20 and |K| = 5, 10, 20. Five instances of each size, each $|\mathcal{F}|$ and each |K| were tested. We will consider the average results obtained for these instances.

The real instances are extracted from operational networks and have been provided by the french telecommunications operator France Télécom. These instances have 6 to 18 nodes and \mathcal{F} with 11 to 32 edge sets. Actually France Télécom has provided the optical network and the routing between every pair of nodes in this network. With an edge *f* of the IP network, we associate the routing path of the optical network between the switches corresponding to the IP router endpoints of *f*. Using these paths, we have computed $\mathcal{F} = \{F_e \subseteq E^1, e \in E^2\}$ where F_e is the set of edges *f* of E^1 such that *e* belongs to the path associated with *f*.

The number of commodities is between 5 and 20. We randomly generated the endpoints of the commodities. The amount of each commodity is calculated with the gravity model. This model, introduced by Reilly (1931) and inspired from Newton's law of gravitation, permits to predict the movement of people and commodities between cities and continents. The model uses the distance and the population of both, the origin and destination cities. The general expression of the gravity model for a commodity (o_k , d_k , v_k) of *K* is $p^{\alpha}p^{\beta}$

 $v_k = \frac{P_{ok}^{p} P_{dk}^{d}}{d_{ok,d_k}}$ where P_{o_k} and P_{d_k} are the populations of the origin and destination cities, respectively, and d_{o_k,d_k} represents the euclidean distance between o_k and d_k . The amount of traffic we consider is rv_k where r is a constant. We fix r = 1.2 and r = 0.8 in order to have different amounts

of traffic between two cities in the two directions, and then break the symmetry.

Usually the cost associated with a link in the client network is related to the corresponding routing path in the optical network, and then depends on the cost of this path. Actually, the cost c(f) of link f in the IP network is given by

$$c(f) = c + \kappa(f),$$

where *c* is a fixed cost representing the equipments of the extremity ports on the routers of *f* in the IP layer, and $\kappa(f)$ is a cost depending on the length of the path P_f corresponding to *f* in the optical network.

The installation of an optical link usually yields a fixed cost on each extremity of this link. Hence a first estimation of the optical cost $\kappa(f)$ is the sum of the fixed costs of the optical links on P_f . As these fixed costs can be considered the same in the optical network, a good approach would be to consider a cost $\kappa(f)$ proportional to the number of the optical links on P_f . So, a first natural function $\kappa(f)$ consists of the number of links (hops) in the optical path between the switching nodes corresponding to the endpoints of f. Here we assume that there is a fixed cost associated with each optical link. This cost is considered once the corresponding link is used. Then the cost c(f) is given in this case by $c + |P_f|$.

In the various tables, the entries are:

- $|V^1|$: the number of nodes of G^1 ,
- $|\mathcal{F}|$: the number of sets F_e ,
- |K| : the number of demands,
- FV :

the number of flow variables for the node-arc formulation and the

number of generated paths for the path formulation,

- NC : the number of generated cut inequalities,
- $\operatorname{NRC}\;$: the number of generated arc residual capacity inequalities,
- NS : the number of generated saturation inequalities (only for SND-MF_s problem),
- NCC : the number of generated cut-cycle inequalities,
- NSP : the number of generated star-partition inequalities,
- NT : the number of generated nodes in the Branch-and-Cut tree,
- o/p : the number of problems solved to optimality over the number

of instances tested (only for random instances),

- Copt : the value of the optimal solution,
- Gap : the relative error between the best upper bound (the optimal value if the problem has been solved to optimality) and the lower bound achieved by the cutting plane phase (before branching),
- TT : the total CPU time in h:mm:ss.

Our first series of experiments concerns the problem SND-MF_m (with multiple links) for the random instances. In these experiments, we have considered three instances for each size. Table 1 reports the average results obtained for these instances with both algorithms based on the

node-arc and the path formulations.

As we can observe, all the instances with 6 nodes have been solved to optimality. Moreover, they have been solved in less than 5 min (and in less than 2 min using the path formulation based algorithm), except those with $|\mathcal{F}| = 20$ and |K| = 20. These needed around 33 min to be solved to optimality using the node-arc formulation based algorithm. We also remark that for the instances with a reduced number of commodities, the problem seems to be much easier to solve. In fact, for all the instances with 5 commodities, less than one hour was needed to get the optimal solution except for the instances with 10 nodes and $|\mathcal{F}| = 20$.

The instances with 10 and 20 commodities and $|\mathcal{F}| = 20$ seem to be harder to solve. In fact, none of these instances could be solved to optimality with the node-arc formulation within the time limit, when the number of nodes exceeds 8. The results are more promising with the path formulation where 5 instances among 12 have nevertheless been solved in an average time sometimes less than two hours.

Among the 54 tested instances, 17 could not be solved within the time limit of five hours using the node-arc formulation based algorithm, and only 12 instances with that based on the path formulation. So, this would imply that the latter algorithm is more efficient. However for 10 nodes, $|\mathcal{F}| = 10$ and |K| = 20, two instances have been solved with the first algorithm but they did not with the second one.

The number of flow variables of the node-arc formulation is fixed and only depends on $|V^1|$, $|\mathcal{F}|$ and |K|. This is not however the case for the flow variables of the path formulation. We remark that the number of the flow variables generated, using this formulation, is generally smaller than that of the node-arc formulation. For example if we consider the instance with 8 nodes, 20 commodities and $|\mathcal{F}| = 10$, we have that the number of flow variables is 11200 whereas the number of generated paths is 4100. This may explain the fact that some instances could be solved to optimality using the path formulation whereas they could not using the node-arc one. Moreover the CPU times obtained with the path formulation based algorithm are less than those obtained with the node-arc formulation based algorithm except for the instances with 10 nodes and $|\mathcal{F}| = 10$. The difference of time is sometimes big. For example, for the instances with 6 nodes, $|\mathcal{F}| = 20$ and |K| = 20, the time goes from less than 2 min to more than 30 min and for 8 nodes, $|\mathcal{F}| = 10$ and |K| = 20, it goes from 20 min to more than 4 h. Therefore the path formulation seems to give better results than the node-arc formulation.

We can also remark that for most of the instances, a significant number of cut and arc residual capacity inequalities (for the node-arc formulation) have been generated. This implies that these inequalities are useful for the random problems. However the cut-cycle and starpartition inequalities do not seem to play an important role for this type of instances.

Table 2 presents the results for the SND-MF_m problem for the real instances with both path and node-arc formulation based algorithms. Here the cost function represents, for each link of the IP network, the number of links of the optical network used in the associated path. This cost function is then integral.

It appears from the table that the difficulty to solve the instances increases with the number of nodes and the number of commodities in the network. All the instances with 5 commodities and up to 14 nodes have been solved in less than one hour. Also for the instances with 10 commodities, we have obtained an optimal solution for all the instances with no more than 10 nodes in less than 3 h with the node-arc formulation and in less than 45 min with the path formulation. The instance with 16 nodes and 10 commodities has also been solved to optimality.

In addition, we remark that for the instances with 15 and 20 commodities only those with no more than 8 nodes could be solved to optimality. For all the instances which have not been solved in the time limit, we have nevertheless obtained feasible solutions (given in italic). Also, we can remark that for some instances, we have obtained a relatively small gap. This is for example the case for the instance with 12 nodes and 10 commodities where the gap is 6%. For the larger instances, the gap does not exceed 18%.

Moreover we notice that all the instances solved with the algorithm based on the node-arc formulation have also been solved with the one based on the path formulation, except that with 14 nodes and 10 commodities. Furthermore, the time needed was much lower. In fact, as it can be observed, for the instance with 8 nodes and 15 commodities, the time passes from 2 h 12 min to 18 min and for that with 10 nodes and 10 commodities, it passes from 2 h 45 min to 43 min. As regards the instances which have not been solved with the two algorithms in the time limit, we can remark that the value of the best feasible solution we have found with the path formulation is cheaper than that obtained with the node-arc one and this is for most of the instances.

Results for real instances for the SND-MF_s problem.

As for the random problems, for most of the real instances, a significant number of cut inequalities have been generated. It also appears that the cut-cycle inequalities and star-partition inequalities are more effective for this type of instances. This can be explained by the fact that the way the sets F_e 's are built, it is easier to find cut-cycle and starpartition configurations. It seems that the node-arc formulation permits to generate more cut-cycle inequalities (72 constraints generated for all the instances against 58 with the path formulation) and the path formulation privileges rather the star-partition inequalities (37 constraints generated against only 22 with the node-arc formulation).

For these instances, we can also observe that the number of flow variables generated for the path formulation is much lower than the one used in the node-arc one. For example, the instance with 16 nodes and 10 commodities has used 69600 flow variables for the first formulation and only 19934 flow variables in the second one.

Tables 3 and 4 report the results for the SND-MF_s problem (single version). As in the previous experiments related to the SND-MF_m problem, we have considered random and real instances. We have tested our two algorithms on the same instances. Table 3 reports the results for the random instances. As for the multiple case, we have tested three instances for each size, Table 3 gives the average results. Also here we have used the saturation constraints (33) which are valid for this variant of the problem.

We can note that all the instances with 6 and 8 nodes have been solved to optimality with at least one of the algorithms. This is also the case for all the instances with $|\mathcal{F}| = 10$ except that with 10 nodes and 20 commodities, and for the instances with $|\mathcal{K}| = 5$, except two of the instances with 10 nodes and $|\mathcal{F}| = 20$.

Among the 9 instances with 10 nodes and $|\mathcal{F}| = 20$, only one has been solved in the time limit of 5 h. The gap obtained is generally not very high (less than 18%). Also here both algorithms seem to have similar performance. In fact most of the instances solved by one have also been solved by the other.

The saturation constraints appear in a small proportion with respect to the cut and arc residual capacity inequalities. This does not imply that these inequalities are not necessary for this variant of the problem. On the contrary, they have been quite utile for solving the random instances. Also we notice that for the multiple variant of the problem, the number of generated cut-cycle and star-partition inequalities is also not very significant in this case.

Table 4 presents the results obtained for the SND-MF_s problem for the real instances. We can remark that in general, the results based on the path formulation, obtained with the Branch-and-Cut-and-Price algorithm, are better than those based on the node-arc formulation. In fact, several instances which have not been solved in the time limit with the latter formulation, have been solved with the former one, and even

Optical network

Commodities

Fig. 6. A real French instance with 10 nodes, $|\mathcal{F}| = 25$ and 10 commodities.

in less than 30 min for some of them like that with 8 nodes and 20 commodities. Furthermore, for the path formulation based algorithm, the CPU time is much smaller. Also for most of the instances which could not be solved in the time limit, the gap has significantly decreased using the path formulation, as for example for the instance with 12 nodes and 15 commodities, the gap passes from 18,22 to 9,82.

It seems however that the SND-MF problem in its simple version is easier to solve. In fact, for the random instances and the node-arc formulation, only 11 among the 54 instances could not be solved for the SND-MF_s problem against 17 for the SND-MF_m problem. The difference is less important for the path formulation. Here the number of solved instances is almost the same, but the CPU time needed for the SND-MF_s problem is generally lower.

For several instances presented in the previous tables, we have not obtained an optimal solution. In order to evaluate the performance of our algorithms in providing provably near-optimal solutions in reasonable time, we have noted the value of the best feasible solution after each hour of computation. Table 5 shows the evolution of the current feasible solution for these instances. The different columns of this table represent in addition to the number of nodes of G^1 ($|V^1|$), the number of sets F_e ($|\mathcal{F}|$) and the number of demands |K|,

- Algo : the type of algorithm (*na* (resp. *p*)) means that the used algorithm is based on the node-arc (resp. path) formulation,
- BS : the value of the best founded solution,
- ${\rm Gap2}\;$: the relative error between the best feasible solution and the

best lower bound.

The first part of the table concerns the $SND-MF_m$ problem whereas the second one is related to the $SND-MF_s$ one. The lines are presented in pairs, one for the node-arc formulation and one for the path formulation. When there is only one line, this means that one of the formulation has permitted to find the optimal solution in the time limit.

We remark that for most of the instances, we have a very near-optimal solution. For example, for the SND-MF_s problem and the instance with 16 nodes, the gap is 1,32%. However for harder instances, the best feasible solution is still distant of the optimal one. For example, the gap

Fig. 7. IP network solutions.

for the instance with 18 nodes is near 15% for the SND-MF_m problem and 6% (resp. 19%) for the SND-MF_s problem for the node-arc formulation (resp. the path formulation).

We can note that, as time elapsed, the gap decreases. Actually we have observed that the best solution decreases and the global lower bound increases for almost all the instances. A last remark we can give is that a very good feasible solution could be found in 1 or 2 h. For example, for the instance with 12 nodes the gap is 5,62% (resp. 1,68%) after 1 h (resp. 2 h) with the path formulation for the SND-MF_s problem.

Finally, we present a little real french instance with 10 nodes, $|\mathcal{F}| = 25$ and |K| = 10. Fig. 6 presents the optical network and the set of commodities.

Fig. 7 gives the solutions for the two variants of the problem. The dashed lines represent the edges with capacity 2.5 Gbits and the solid ones the edges with capacity 10 Gbits. For the SND- MF_m problem, the number 2 on some edges indicates that we have installed two links between the towns, endpoints of the edge. The optimal solutions shown in Fig. 7 have been obtained with the Branch-and-Cut-and-Price algorithm based on the path formulation in 43 min for the multiple version and in only 10 s for the simple one.

6. Concluding remarks

In this paper we have considered the multilayer survivable network design problem which has applications to the design of reliable IP-overoptical network. We have considered the capacity dimensioning of the network. We have proposed two integer programming formulations for each of the two variants of the problem, simple and multiple. We have identified some valid inequalities, and described necessary conditions and sufficient conditions for a class of inequalities to define facets. Using this, we have developed Branch-and-Cut and Branch-and-Cut and-Price algorithms for the problems and presented extensive computational results. These ones show that the path formulation based algorithm performs better than the one based on the node-arc formulation. The experimental results also show the effectiveness of the capacity demand cut, the cut-cycle and the star-partition inequalities for the problem.

Both algorithms have only been tested for small instances with up to 10 nodes for the random instances and to 18 nodes for the reals ones. First, this was because the real instances for such problems are generally of small size. Also, we have remarked that when the number of scenarios and demands gets increasing, as the number of variables becomes huge, the algorithm could not solve the problem because of memory and time limit. One way to improve the algorithm would be to introduce a preprocessing step which may reduce the size of the problem to be solved. Another way would be to use a primal heuristic. However this may not be easy to devise because finding paths that respect the failures in both, simple and multiple versions, would not be easy.

Other variants of the multilayer network design problem are of interest for telecommunication operators and merit to be investigated. In particular those in which IP and optical layers should be treated simultaneously. This is our direction of future research.

Also a more general variant of the problem, which merits to be studied, is when bounds are considered on the paths of the IP network. This issue has been treated in the literature in the single-layer case (Dahl, Huygens, Mahjoub, & Pesneau, 2006; Fortz, McCormick, Mahjoub, &

Fig. 8. Construction of a solution for SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*).

We are grateful to the anonymous referees for their constructive

comments that permitted to improve the presentation of the paper.

Pesneau, 2006; Huygens, Labbé, Mahjoub, & Pesneau, 2007; Huygens, Mahjoub, & Pesneau, 2004). An other interesting question would be to consider integer flows. This concept has also been investigated for the single-layer networks but without considering survivability (Barnhart et al., 2000; Brunetta, Conforti, & Fischetti, 2000).

Appendix A. Proof of Theorem 6

Proof. We use ideas similar to those developed in Magnanti et al. (1995). Let us denote inequality (27) by

 $a^{1}x^{1} + a^{2}x^{2} \ge \alpha,$ (43) and let

Acknowledgment

 $b^1 x^1 + b^2 x^2 + \lambda f \ge \beta,$

be a facet defining inequality of SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*) such that the face defined by (43) is contained in that defined by (44). Let $L = \{(x^1, x^2, f) \in \text{SND-MF}^{na}_m(G, \mathcal{F}, K) | a^1x^1 + a^2x^2 = \alpha\}.$

We first construct a feasible solution which satisfies (43) with equality. For each commodity k such that o_k and d_k are in W, as G(W) is \mathcal{F} -connected, for all $j \in \{1, ..., t\}$, there exists a path P_j^k fully contained in $G_j(W)$, which connects o_k and d_k . If we install $\begin{bmatrix} \frac{\omega_k}{4\mu} \\ \frac{\omega_k}{4\mu} \end{bmatrix}$ high capacities on each edge which belongs to at least one path P_j^k , then we can send a flow of ω_k along the path P_j^k from o_k to d_k for each failure *j*. By adding successively, in a similar way, the necessary capacity for all commodities, we obtain a feasible dimensioning for the edges of E(W) according to the commodities of *W*. For the edges in $E(\overline{W})$, we similarly associate, for each commodity *k* such that o_k and $d_k \in \overline{W}$ and for each $j \in \{1, ..., t\}$, a path \overline{P}_j^k between o_k and d_k . We install capacities on these paths in a similar way as in G(W).

Now, consider an edge $u_i v_i$ of $\delta_{G_i}(W)$ such that $u_i \in W$ and $v_i \in \overline{W}$.

Let $I_i = \{j \in \{1, ..., t\} \setminus \{i\} | u_i v_i \in F_j\}$. Then for all $j \in I_i$, there exists an edge, say $u_j v_j$, in $\delta(W) \cap F_i$ such that $u_j v_j \neg \in F_j$. In fact, if this is not the case, then there would exist $j \in I_i$ such that $\delta(W) \cap F_i \subseteq \delta(W) \cap F_j$. As by definition of I_i , $u_i v_i \in F_j \setminus F_i$, we would have $\delta(W) \cap F_i \subset F_j$. But this is a contradiction with Condition (3) of Theorem 5 (see Fig. 8).

Let $k \in \gamma(W)$ be a commodity accross the cut. As the graph G(W) (resp. $G(\overline{W})$) is \mathcal{F} -connected, for all $j \in \{1, ..., t\} \setminus I_i$, there exists a path Q_j^k (resp. \overline{Q}_j^k) between o_k and u_i (resp. v_i and d_k) in $G_j(W)$ (resp. $\overline{G_j}(W)$). For $j \in I_i$, by the previous remark, there is an edge $u_j v_j$ of $(\delta(W) \cap F_i) \setminus F_j$. We may suppose that $u_j \in W$ and $v_j \in \overline{W}$. For the commodity k, and for all $j \in I_i$, similarly, there is a path Q_j^k (resp. \overline{Q}_j^k) between o_k and u_j (resp. v_j and d_k) in $G_i(W)$ (resp. $\overline{G_i}(W)$).

Now, we can complete the partial dimensioning already performed in W and \overline{W} . We install for commodity k, $\begin{bmatrix} \omega_k \\ 4\mu \end{bmatrix}$ high capacities on each edge that belongs to at least one path Q_j^k , \overline{Q}_j^k , j = 1..., t. We then add successively these capacities for each commodity of $\gamma(W)$. These new capacities, added to those already installed in W and \overline{W} , permit to have a feasible dimensioning for all the commodities and all the edges of $E(W) \cup E(\overline{W})$. This dimensioning of the edges of $E(W) \cup E(\overline{W})$ can be given as follows,

$$\begin{aligned} x_{uv}^{1} &= 0 \quad \text{for all } uv \in E(W) \cup E(\overline{W}), \\ x_{uv}^{2} &= \sum_{\substack{k \mid o_{k}, d_{k} \in W \\ uv \in \cup_{j} p_{j}^{k}}} \left[\frac{\omega_{k}}{4\mu} \right] + \sum_{\substack{k \in \gamma(W) \\ uv \in \cup_{j} Q_{j}^{k}}} \left[\frac{\omega_{k}}{4\mu} \right] \quad \text{for all } uv \in E(W), \\ x_{uv}^{2} &= \sum_{\substack{k \mid o_{k}, d_{k} \in W \\ uv \in \cup_{j} \overline{P}_{j}^{k}}} \left[\frac{\omega_{k}}{4\mu} \right] + \sum_{\substack{k \in \gamma(W) \\ uv \in \cup_{j} \overline{Q}_{j}^{k}}} \left[\frac{\omega_{k}}{4\mu} \right] \quad \text{for all } uv \in E(\overline{W}). \end{aligned}$$

As $D_W \ge 4$, for the edges of $\delta(W)$, we can consider the following dimensioning,

$$\begin{split} x_{u_j v_j}^1 &= D_W \mod 4 & \text{ for all } j \in I_i \cup \{i\}, \\ x_{uv}^1 &= 0 & \text{ for all } uv \in \delta(W) \setminus \bigcup_{j \in I_i \cup \{i\}} \{u_j v_j\}, \\ x_{u_j v_j}^2 &= \lfloor \frac{D_W}{4} \rfloor & \text{ for all } j \in I_i \cup \{i\}, \\ x_{uv}^2 &= 0 & \text{ for all } uv \in \delta(W) \setminus \bigcup_{j \in I_i \cup \{i\}} \{u_j v_j\}. \end{split}$$

Also consider the flows on the paths P_i^k , \overline{P}_i^k , Q_i^k , \overline{Q}_i^k , j = 1, ..., t, given by

for all k such that o_k , $d_k \in W$ (resp. o_k , $d_k \in \overline{W}$),

$$\begin{aligned} f_{uv}^{k,i} &= \omega_k \quad j = 1, ..., t, \ uv \in P_j^k, \ (\text{resp. } uv \in \overline{P}_j^k) \ \text{and} \ uv \ \text{traversed from} \ u \\ & \text{to} \ v \ \text{in} \ P_i^k(\text{resp.}, \overline{P}_j^k), \end{aligned}$$

for all
$$k \in \gamma(W) j = 1, ..., t, uv \in Q_i^k$$
, (resp. $uv \in \overline{Q}_i^k$)

 $f_{uv}^{k,i} = \omega_k$ and uv traversed from u to v in Q_j^k (resp. \overline{Q}_j^k),

$$f_{uv}^{k,i} = \omega_k u = u_j(v_j), v = v_j(u_j)j \in I_i \cup \{i\},$$

$$f_{uv}^{k,i} = 0 \quad \text{otherwise}$$

 $f_{uv}^{\kappa,\iota} = 0$ otherwise.

(45)

(46)

(44)

The solution (x^1, x^2, f) given by (45)–(47) is feasible for SND-MF^{ma}_m(G, \mathcal{F}, K). Let $pq \in E(W) \cup E(\overline{W}) \cup (F_i \cap \delta(W))$. And let (x^1, x^{2r}, f') be the solution such that

 $\begin{aligned} x_{uv}^{1\prime} &= x_{uv}^{1} & \text{for all } uv \neq pq, \\ x_{pq}^{1\prime} &= x_{pq}^{1} + 1, \\ x^{2\prime} &= x^{2}, \\ f' &= f. \end{aligned}$

Clearly, $(x^{1'}, x^{2'}, f')$ is feasible for SND-MF^{*na*}_{*m*}(*G*, \mathcal{F} , *K*). Furthermore, (x^1, x^2, f) and $(x^{1'}, x^{2'}, f')$ satisfy inequality (43) with equality. In consequences, both solutions satisfy inequality (44) with equality. This yields $b_{pq}^1 = 0$. Similarly, one can show that $b_{pq}^2 = 0$. As pq is an arbitrary edge of $E(W) \cup E(\overline{W}) \cup (F_i \cap \delta(W))$, we then have $b_{uv}^1 = b_{uv}^2 = 0$ for all $uv \in E(W) \cup E(\overline{W}) \cup (F_i \cap \delta(W))$.

Now, consider the edge $u_i v_i$ (introduced above) and the solution $(\tilde{x}^1, \tilde{x}^2, \tilde{f})$ such that

$$\begin{split} \widetilde{x}_{u_l v_l}^1 &= x_{u_l v_l}^1 + 4, \\ \widetilde{x}_{u v}^1 &= x_{u v}^1 & \text{for all } u v \in E \text{ such that } u v \neq u_l v_l, \\ \widetilde{x}_{u_l v_l}^2 &= x_{u_l v_l}^2 - 1, \\ \widetilde{x}_{u v}^2 &= x_{u v}^2 & \text{for all } u v \in E \text{ such that } u v \neq u_l v_l, \\ \widetilde{f} &= f. \end{split}$$

The solution $(\tilde{x}^1, \tilde{x}^2, \tilde{f})$ is defined from (x^1, x^2, f) by replacing a high capacity on $u_i v_i$ by 4 small ones. Hence, this solution is feasible. Furthermore, as $(\tilde{x}^1, \tilde{x}^2, \tilde{f})$ satisfies (43) with equality, it also satisfies (44) with equality. This implies that $4b_{u_iv_i}^1 = b_{u_iv_i}^2$. As u_iv_i is an arbitrary edge of $\delta_{G_i}(W)$, we then get

 $b_{uv}^2 = 4b_{uv}^1$ for all $uv \in \delta(W) \setminus F_i$.

Consider again an edge $pq \in E(W) \cup E(\overline{W}) \cup F_i$ and the solution (x^1, x^2, f) introduced above. Let $k' \in K$ be a commodity and $j' \in \{1, ..., t\}$ a failure. Consider $(\hat{x}^1, \hat{x}^2, \hat{f})$ given by

$$\begin{split} &\hat{x}^{1} = x^{1}, \\ &\hat{x}^{2} = x^{2}, \\ &\hat{f}_{pq}^{k',j'} = f_{pq}^{k',j'} + \varepsilon, \\ &\hat{f}_{qp}^{k',j'} = f_{qp}^{k',j'} + \varepsilon, \\ &\hat{f}_{uv}^{k,j} = f_{uv}^{k,j} \text{ for all } uv \in E \setminus \{pq\}, \text{ for all } k \in K, \text{ for all } j \in \{1, ..., t\}, \end{split}$$

where $0 < \varepsilon < \frac{1}{2}$. Note that as the capacity of edge pq is sufficiently big, we have a residual capacity to carry more flow. In consequences, $(\hat{x}^1, \hat{x}^2, \hat{f})$ is feasible. Moreover, this solution satisfies inequality (43), and hence (44), with equality. As (x^1, x^2, f) also satisfies (44) with equality, we obtain $\lambda_{pq}^{k',j'} \varepsilon + \lambda_{qp}^{k',j'} \varepsilon = 0$ implying that $\lambda_{pq}^{k',j'} = -\lambda_{qp}^{k',j'}$. As pq is an arbitrary edge of $E(W) \cup E(\overline{W}) \cup F_i$, and k' and j' are arbitrary in K and $\{1, ..., t\}$, respectively, we obtain

 $\lambda_{uv}^{k,j} = -\lambda_{vu}^{k,j}$ for all $uv \in E(W) \cup E(\overline{W}) \cup F_i$, for all $k \in K$ and all $j \in \{1, ..., t\}$.

Now consider again the edge $u_i v_i$ of $\delta(W) \setminus F_i$. By Condition (5) of Theorem 5, if we consider the solution (x^1, x^2, f) , as $u_i v_i$ has a sufficiently big capacity, we can add more flow on this edge. In a similar way we can show that $\lambda_{u_i v_i}^{k',j'} = -\lambda_{v_i u_i}^{k',j'}$. And as $u_i v_i$ is chosen arbitrarly in $\delta_{G_i}(W)$, like k' and j' in K and $\{1, ..., t\}$, we obtain

 $\lambda_{uv}^{k,j} = -\lambda_{vu}^{k,j}$ for all $uv \in \delta_{G}(W)$, for all $k \in K$ and all $j \in \{1, ..., t\}$.

We have then shown that

 $\lambda_{uv}^{k,i} = -\lambda_{vu}^{k,i}$ for all $uv \in E$, for all $k \in K$ and all $j \in \{1, ..., t\}$.

We now show that $\sum_{k \in K} \sum_{uv \in E} (\lambda_{uv}^{k,j} f_{uv}^{k,j} + \lambda_{vu}^{k,j} f_{vu}^{k,j})$ is a constant for all failure j = 1, ..., t, by showing that the sum of the coefficients, corresponding to any cycle in the network, equals zero. Let Δ denote the set of cycles in D = (V, A). Consider a failure $j \in \{1, ..., t\}$ and a particular cycle $\xi \in \Delta$. Let $\lambda_{\xi}^{k,j} = \sum_{(u,v)\in\xi} \lambda_{uv}^{k,j}$. We will show that $\lambda_{\xi}^{k,j} = 0$ for all cycle $\xi \in \Delta$. Call ξ an *s*-intersection cycle with respect to the cut $\delta_G(W)$ if ξ contains exactly *s* arcs of $\delta_G(W)$. Note that *s* must be even as ξ is a cycle.

If ξ is a 0-intersection cycle, then ξ is completely contained in W or \overline{W} . We suppose w.l.o.g., that ξ is in W. Let $k \in K$ and $(\check{x}^1, \check{x}^2, \check{f})$ be the solution given by

$$\begin{split} \dot{x}_{uv}^1 &= x_{uv}^1 + 1 & \text{for all } uv \in E(W) \text{ such that } (u, v) \text{ ou } (v, u) \in \xi, \\ \dot{x}_{uv}^1 &= x_{uv}^1 & \text{for all } uv \in E(W) \text{ such that } (u, v) \text{ ou } (v, u) \neg \in \xi, \\ \dot{x}_{uv}^2 &= x_{uv}^2 & \text{for all } uv \in E, \\ \dot{f}_{uv}^{k,j} &= f_{uv}^{k,j} + 1 & \text{for all } (u, v) \in \xi, \\ \dot{f}_{uv}^{k,j} &= f_{uv}^{k,j} & \text{for all } (u, v) \neg \in \xi, \\ \dot{f}_{uv}^{k,h} &= f_{uv}^{k,h} & \text{for all } (u, v) \in A, \text{ for all } h \in \{1, ..., t\} \setminus \{j\}. \end{split}$$

(48)

Here, we construct solution $(\check{x}^1, \check{x}^2, \check{f})$ from solution (x^1, x^2, f) by installing a small capacity on all the edges in ξ and by sending an additional unit of flow on ξ . Solution ($\dot{x}^1, \dot{x}^2, \dot{f}$) is still feasible and satisfies (43) with equality. Hence ($\dot{x}^1, \dot{x}^2, \dot{f}$) satisfies (44) with equality, and in consequence we get

$$\sum_{uv \in E(W)} b_{uv}^1 x_{uv}^1 - \sum_{uv \in E(W)} b_{uv}^1 \check{x}_{uv}^1 + \sum_{(u,v) \in \xi} (\lambda_{uv}^{k,j} f_{uv}^{k,j} - \lambda_{vu}^{k,j} f_{vu}^{k,j}) = 0.$$

As $b_{uv}^1 = 0$ for all $uv \in E(W)$, we obtain $\sum_{(u,v)\in\mathcal{F}} -\lambda_{uv}^{k,j} = 0$, and then $\lambda_{\mathcal{F}}^{k,j} = 0$. As cycle ξ , the commodity k and the failure j are arbitrary, we have then shown that

 $\lambda_{\xi}^{k,j} = 0$ for all 0-intersection cycle $\xi \in \Delta$, for all $k \in K$ and for all $j \in \{1, ..., t\}$.

Now suppose that ξ is a 2-intersection cycle. Assume that (p, \overline{p}) and (q, \overline{q}) are the cutset arcs belonging to $\delta_{c}(W) \cap \xi$ with $p, q \in W$ and $\overline{p}, \overline{q} \in \overline{W}.$

If p = q and $\overline{p} = \overline{q}$, then ξ can be decomposed into three cycles: a 0-intersection cycle denoted by ξ_1 , contained in W, a 0-intersection cycle denoted by ξ_2 contained in \overline{W} and a cycle formed by the arcs (p, \overline{p}) and $(\overline{p}, p) = (\overline{q}, q)$. We then have $\lambda_{\xi}^{k,j} = \lambda_{\xi_1}^{k,j} + \lambda_{p\overline{p}}^{k,j} + \lambda_{\overline{p}p}^{k,j} + \lambda_{\overline{p}p}^{k,j}$. As ξ_1 and ξ_2 are 0-intersection cycles, $\lambda_{\xi_1}^{k,j} = \lambda_{\xi_2}^{k,j} = 0$ and by (48), we have $\lambda_{p\overline{p}}^{k,j} = -\lambda_{\overline{p}p}^{k,j}$. Thus $\lambda_{\xi}^{k,j} = 0$.

Now suppose that $p\overline{p} \neq q\overline{q}$ and one of the two edges $p\overline{p}$ or $q\overline{q}$ belongs to F_i . We suppose, w.l.o.g., that $q\overline{q} \in F_i$ and $p\overline{p} \neg \in F_i$. Let $p\overline{p}$ be the edge which belongs to $\delta_{G_i}(W)$. One can construct a feasible solution $(\check{x}^1, \check{x}^2, \check{f})$ in a similar way as (x^1, x^2, f) (given above for the edge $u_i v_i$). Remark that $\check{x}_{p\overline{p}}^{1} = D_{W} \mod 4$ and $\check{x}_{p\overline{p}}^{2} = \lfloor \frac{D_{W}}{4} \rfloor$. Consider the solution obtained from $(\check{x}^{1}, \check{x}^{2}, \check{f})$ by installing a small capacity on all the edges of $\hat{\xi} \cap (E(W) \cup E(\overline{W}) \cup F_i)$, and by sending ε units of flow on ξ (for a certain $\varepsilon > 0$). The additional flow is possible since by Condition (5) of Theorem 5, there is a positive residual capacity on the edge $p\overline{p}$. This new solution is feasible. As both solutions satisfy (43) with equality and hence (44), we get $\lambda_{\xi}^{k,j}=0.$

If $p\overline{p} = q\overline{q}$ and $p\overline{p}$, $q\overline{q} \neg \in F_i$, we define a solution $(\dot{x}^1, \dot{x}^2, \dot{f})$ by considering for the edges of the cut $\delta_{G_i}(W)$ the following values

$$\begin{split} \dot{x}_{p\overline{p}}^{1} &= D_{W} \mod 4, \\ \dot{x}_{uv}^{1} &= 0 & \text{for all } uv \in \delta_{G_{l}}(W), \\ \dot{x}_{p\overline{p}}^{2} &= \lfloor \frac{D_{W}}{4} \rfloor - 1, \\ \dot{x}_{q\overline{q}}^{2} &= 1, \\ \dot{x}_{uv}^{2} &= 0 & \text{for all } uv \in \delta_{G_{l}}(W) \backslash \{p\overline{p}, q\overline{q}\}. \end{split}$$

For the dimensioning of E(W) and $E(\overline{W})$, we suppose that we have installed a sufficient capacity which permits to carry the flows of the commodities in W and \overline{W} on the paths fully contained in G(W) and $G(\overline{W})$. These capacities can be taken as big as we want. So, by Condition (5) of Theorem 5, the commodities of $\gamma(W)$ can be routed in such a way that $p\overline{p}$ and $q\overline{q}$ contain at least ε (for a certain $\varepsilon > 0$) units of residual capacity. This solution is feasible and satisfies (43) and then (44) with equality. Using the residual capacity ε on $p\overline{p}$ and $q\overline{q}$, one can obtain a new feasible solution from $(\dot{x}^1, \dot{x}^2, \dot{f})$ by adding an additional flow ε along ξ for commodity k, and installing a small capacity on the edges of ξ not in $\delta_{G}(W)$. This new solution is also feasible and satisfies (43) and (44) as equalities. As commodity $k \in K$, the failure $j \in \{1, ..., t\}$ and the 2-intersection cycle $\xi \in \Delta$ are arbitrary, we have that

$$\lambda_{\xi}^{k,j} = 0$$
 for all 2-intersection cycle $\xi \in \Delta$, for all $k \in K$
and for all $j \in \{1, ..., t\}$.

(50)

(51)

(49)

Now consider an arbitrary *s*-intersection cycle ξ . Let *k* be a commodity and *j* be a failure. Let ξ be the cycle given by {(s_1 , s_2), (s_2 , s_3), ..., (s_T , s_1)} with $s_1 \in W$. Let (s_{t_1}, s_{t_2}) be the first arc of the cycle ξ that crosses $\delta(W)$ and (s_{t_3}, s_{t_4}) the first subsequent arc that re-enters set W. Note that cycle $\xi' = \{(s_{t_1}, s_{t_2}), \dots, (s_{t_3}, s_{t_4}), (s_{t_4}, s_{t_1})\} \text{ is a 2-intersection cycle. We then have } \lambda_{\xi' \setminus (s_{t_1}, s_{t_4})}^{k,j} = \lambda_{s_{t_1}s_{t_4}}^{k,j}. \text{ So, we can replace the path } \xi' \setminus (s_{t_1}, s_{t_4}) \text{ by the arc } (s_{t_1}, s_{t_4}).$ Repeating this argument, one can construct a 0-intersection cycle ψ that satisfies $\lambda_{\xi}^{k,j} = \lambda_{\psi}^{k,j}$. As k and j are arbitrary, we obtain that

$$\begin{aligned} \lambda_{\xi}^{k,j} &= 0 \qquad \text{for all cycle } \xi \in \Delta, \text{ for all } k \in K \\ & \text{and for all } j \in \{1, ..., t\}. \end{aligned}$$

We have shown that $\sum_{k \in K} \sum_{uv \in E} (\lambda_{uv}^{k,j} f_{uv}^{k,j} + \lambda_{vu}^{k,j} f_{vu}^{k,j})$ is a constant, say λ_j , for any failure $j \in \{1, ..., t\}$. We can now show that $b_{uv}^1 = \rho^1$ and $b_{uv}^2 = \rho^2$ for all $uv \in \delta_{G_i}(W)$. Consider the solution (x^1, x^2, f) given in the beginning of the proof, an edge $pq \in \delta_{G_i}(W)$ such that $pq \neq u_i v_i$, a commodity $k' \in K$ and a failure $j \in \{1, ..., t\}$. Let $P(u_i, p)$ be a path from node u_i to p fully contained in W and $P(q, v_i)$ a path from q to v_i in \overline{W} . Consider the solution $(\ddot{x}^1, \ddot{x}^2, \ddot{f})$ such that

 $\ddot{x}_{u_i v_i}^1 = x_{u_i v_i}^1 - 1 = D_W \mod 4 - 1,$ $\ddot{x}_{pq}^{1} = 1,$ $\ddot{x}_{uv}^1 = x_{uv}^1$ for all $uv \in \delta_G(W) \setminus \{u_i v_i, pq\},\$ $\ddot{x}_{uv}^1 = x_{uv}^1 + 1$ for all $(u, v) \in P(u_i, p) \cup P(q, v_i)$, $\ddot{x}_{uv}^1 = x_{uv}^1$ $\ddot{x}_{uv}^2 = x_{uv}^2$ for all $(u, v) \in E(W) \cup E(\overline{W}) \setminus (P(u_i, p) \cup P(q, v_i)),$ for all $uv \in E$.

Define the flows as follows.

$$\begin{split} \ddot{f}_{uv}^{k',j} &= f_{uv}^{k',j} + 1 \quad \text{for all } (u, v) \in P(u_i, p) \cup P(q, v_i), \\ \ddot{f}_{up_i}^{k',j} &= f_{uv_i}^{k',j} - 1, \\ \ddot{f}_{pq}^{k',j} &= 1, \\ \dot{f}_{uv}^{k',j} &= f_{uv}^{k',j} \quad \text{for all } uv \in E \setminus (P(u_i, p) \cup P(q, v_i) \cup \{u_i v_i, pq\}), \\ \dot{f}_{uv}^{k,h} &= f_{uv}^{k,h} \quad \text{for all } uv \in E, \text{ for all } k \in K \setminus \{k'\}, \text{ for all } h \in \{1, ..., t\} \setminus \{j\}. \end{split}$$

Solutions (x^1, x^2, f) and $(\ddot{x}^1, \ddot{x}^2, \ddot{f})$ are feasible and satisfy constraint (43) with equality. In consequence, they also satisfy (44) with equality. This implies that

$$b_{u_l v_l}^1 - b_{pq}^1 - \sum_{uv \in P(u_l, p) \cup P(q, v_l)} \rho_{uv}^1 - \sum_{(u, v) \in P(u_l, p)} \lambda_{uv}^{k', j} - \sum_{(u, v) \in P(q, v_l)} \lambda_{uv}^{k', j} + \lambda_{u_l v_l}^{k', j} - \lambda_{pq}^{k', j} = 0.$$

As $b_{uv}^1 = 0$ for all $uv \in E(W) \cup E(\overline{w})$ and by (48) $\lambda_{uv}^{k',j} = -\lambda_{vu}^{k',j}$, we have

$$b_{u_l v_l}^1 - b_{pq}^1 - \sum_{(u,v) \in P(u_l,p)} \lambda_{uv}^{k',j} - \lambda_{pq}^{k',j} - \sum_{(u,v) \in P(q,v_l)} \lambda_{uv}^{k',j} - \lambda_{v_l u_l}^{k',j} = 0.$$

As $P(u_i, p)$, pq, $P(q, v_i)$ and $v_i u_i$ form a cycle, we have $b_{u_i v_i}^1 - b_{pq}^1 = 0$. As pq was chosen arbitrarily, we obtain $b_{uv}^1 = \rho^1$ for all $uv \in \delta_{G_i}(W)$ for $\rho^1 \in IR$. Since $b_{uv}^2 = 4b_{uv}^1$ for all $uv \in \delta_{G_i}(W)$, we have also $b_{uv}^2 = 4\rho^1$ for all $uv \in \delta_{G_i}(W)$.

Thus, inequality (44) is equivalent to

$$\rho^{1}x^{1}(\delta_{G_{l}}(W)) + 4\rho^{1}x^{2}(\delta_{G_{l}}(W)) + \sum_{j=1}^{l} \lambda_{j} = \lambda,$$

which implies that

$$\rho^1 x^1(\delta_{G_i}(W)) + 4\rho^1 x^2(\delta_{G_i}(W)) = \lambda'$$

where $\lambda' = \lambda - \sum_{i=1}^{t} \lambda_i$. As the face defined by inequality (44) is not empty, $\rho^1 \neq 0$ and we obtain that

$$x^{1}(\delta_{G_{l}}(W)) + 4x^{2}(\delta_{G_{l}}(W)) = \frac{\lambda'}{\rho^{1}} = D_{W}.$$
