Challenges in Deep Reinforcement Learning

What's the problem?

Challenges with core algorithms:

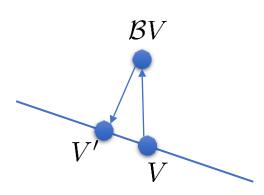

- Stability: does your algorithm converge?
- Efficiency: how long does it take to converge? (how many samples)
- Generalization: after it converges, does it generalize?

Challenges with **assumptions**:

- Is this even the right problem formulation?
- What is the source of *supervision*?

Stability and hyperparameter tuning

- Devising stable RL algorithms is very hard
- Q-learning/value function estimation
 - Fitted Q/fitted value methods with deep network function estimators are typically not contractions, hence no guarantee of convergence
 - Lots of parameters for stability: target network delay, replay buffer size, clipping, sensitivity to learning rates, etc.
- Policy gradient/likelihood ratio/REINFORCE
 - Very high variance gradient estimator
 - Lots of samples, complex baselines, etc.
 - Parameters: batch size, learning rate, design of baseline
- Model-based RL algorithms
 - Model class and fitting method
 - Optimizing policy w.r.t. model non-trivial due to backpropagation through time
 - More subtle issue: policy tends to exploit the model

The challenge with hyperparameters

- Can't run hyperparameter sweeps in the real world
 - How representative is your simulator? Usually the answer is "not very"
- Actual sample complexity = time to run algorithm x number of runs to sweep
 - In effect stochastic search + gradient-based optimization
- Can we develop more stable algorithms that are less sensitive to hyperparameters?

What can we do?

- Algorithms with favorable improvement and convergence properties
 - Trust region policy optimization [Schulman et al. '16]
 - Safe reinforcement learning, High-confidence policy improvement [Thomas '15]
- Algorithms that adaptively adjust parameters
 - Q-Prop [Gu et al. '17]: adaptively adjust strength of control variate/baseline

- More research needed here!
- Not great for beating benchmarks, but absolutely essential to make RL a viable tool for real-world problems

Sample Complexity

gradient-free methods (e.g. NES, CMA, etc.)

10x

fully online methods (e.g. A3C)

10x

policy gradient methods (e.g. TRPO)

10x

replay buffer value estimation methods (Q-learning, DDPG, NAF, SAC, etc.)

model-based deep RL (e.g. PETS, guided policy search)

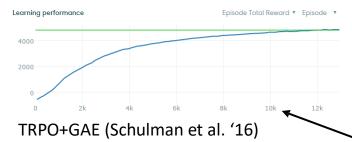

model-based "shallow" RL (e.g. PILCO)

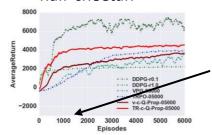

Evolution Strategies as a Scalable Alternative to Reinforcement Learning

half-cheetah (slightly different version)

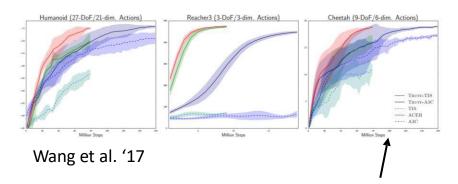

half-cheetah

Gu et al. '16

Chua et a. '18: Deep Reinforcement Learning in a Handful of Trials

10,000,000 steps (10,000 episodes) (~ 1.5 days real time)

1,000,000 steps (1,000 episodes) [~3 hours real time]

10x gap

about 20 minutes of experience on a real robot

100,000,000 steps

(100,000 episodes)

(~ 15 days real time)

Chebotar et al. '17 (note log scale)

The challenge with sample complexity

- Need to wait for a long time for your homework to finish running
- Real-world learning becomes difficult or impractical
- Precludes the use of expensive, high-fidelity simulators
- Limits applicability to real-world problems

What can we do?

- Better model-based RL algorithms
- Design faster algorithms
 - Addressing Function Approximation Error in Actor-Critic Algorithms (Fujimoto et al. '18): simple and effective tricks to accelerate DDPG-style algorithms
 - Soft Actor-Critic (Haarnoja et al. '18): very efficient maximum entropy RL algorithm
- Reuse prior knowledge to accelerate reinforcement learning
 - RL2: Fast reinforcement learning via slow reinforcement learning (Duan et al. '17)
 - Learning to reinforcement learning (Wang et al. '17)
 - Model-agnostic meta-learning (Finn et al. '17)

Scaling & Generalization

Scaling up deep RL & generalization

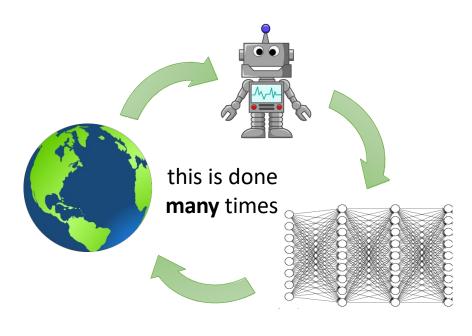

- Large-scale
- Emphasizes diversity
- Evaluated on generalization

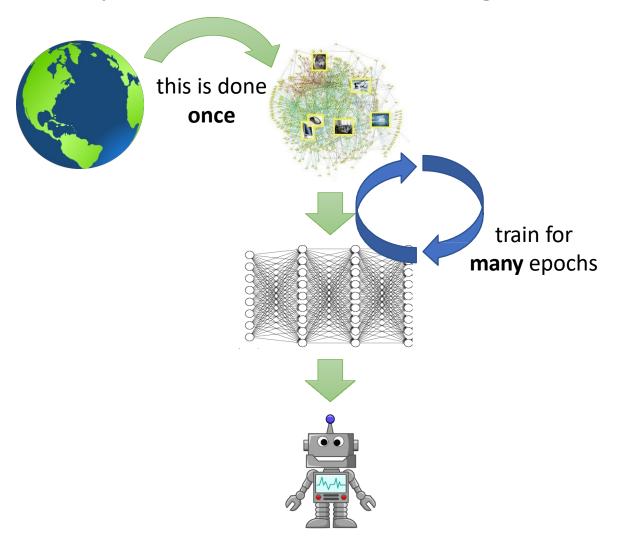

- Small-scale
- Emphasizes mastery
- Evaluated on performance
- Where is the generalization?

RL has a big problem

reinforcement learning

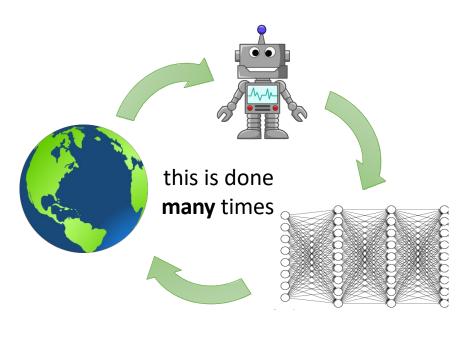

supervised machine learning

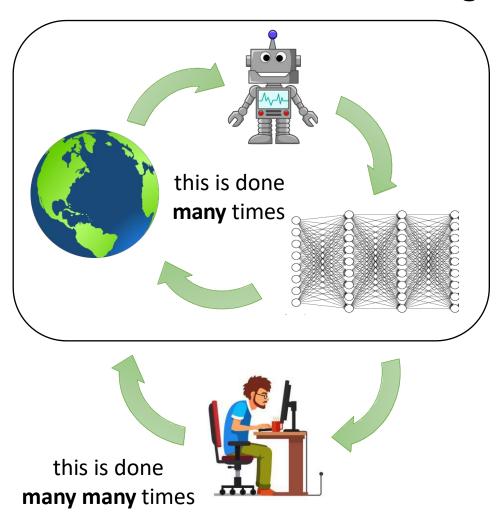

RL has a big problem

reinforcement learning

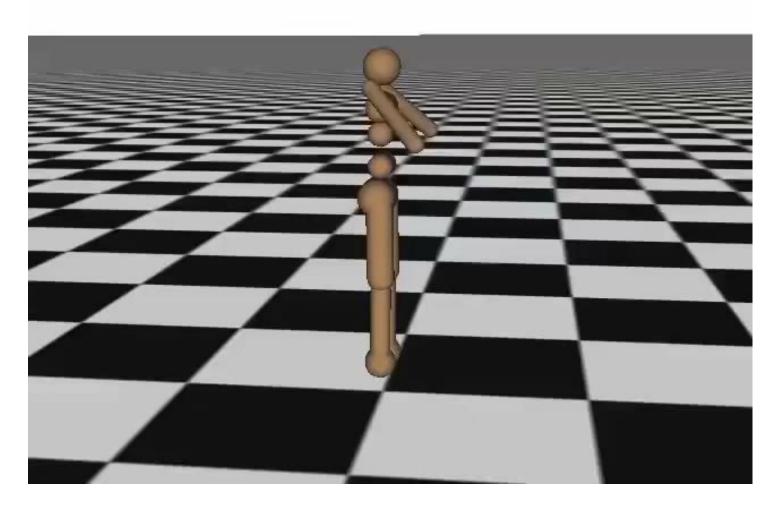

actual reinforcement learning

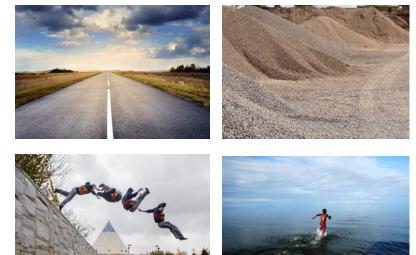

How bad is it?

Iteration 0

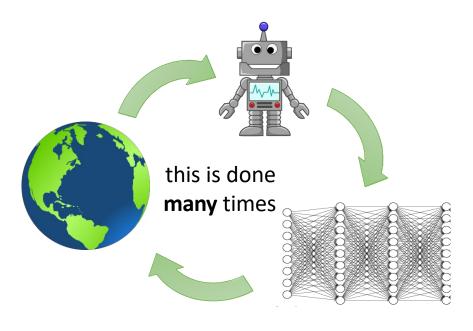

- This is quite cool
- It takes 6 days of real time (if it was real time)
- ...to run on an infinite flat plane

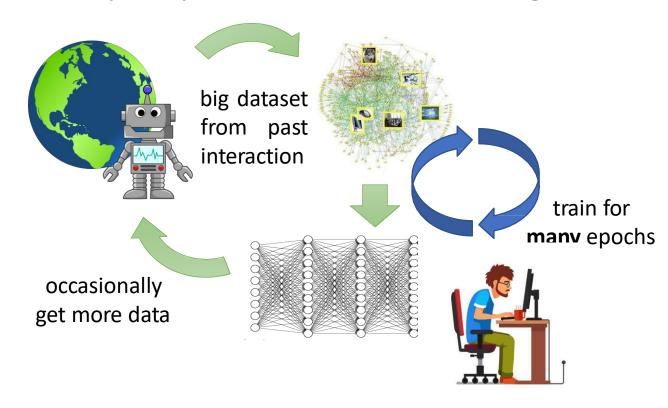

The real world is not so simple!

Off-policy RL?

reinforcement learning

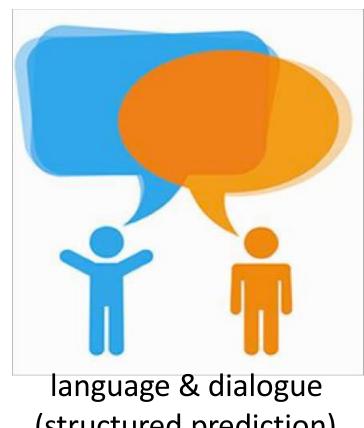

off-policy reinforcement learning

Not just robots!

autonomous driving

(structured prediction)

finance

What's the problem?

Challenges with core algorithms:

- Stability: does your algorithm converge?
- Efficiency: how long does it take to converge? (how many samples)
- Generalization: after it converges, does it generalize?

Challenges with **assumptions**:

- Is this even the right problem formulation?
- What is the source of *supervision*?

Problem Formulation

Single task or multi-task?

The real world is not so simple!

this is where generalization can come from...

maybe doesn't require any new assumption, but might merit additional treatment

pick MDP randomly
$$s_0 \xrightarrow{\pi(\mathbf{a}_0|\mathbf{s}_0)} s_1 \longrightarrow \text{etc.}$$
 MDP 0 in first state $p(\mathbf{s}_0) \xrightarrow{sample} s_0 \xrightarrow{\pi(\mathbf{a}_0|\mathbf{s}_0)} s_1 \longrightarrow \text{etc.}$ MDP 1 $s_0 \xrightarrow{sample} s_0 \xrightarrow{\pi(\mathbf{a}_0|\mathbf{s}_0)} s_1 \longrightarrow \text{etc.}$ MDP 2

Generalizing from multi-task learning

- Train on multiple tasks, then try to generalize or finetune
 - Policy distillation (Rusu et al. '15)
 - Actor-mimic (Parisotto et al. '15)
 - Model-agnostic meta-learning (Finn et al. '17)
 - many others...
- Unsupervised or weakly supervised learning of diverse behaviors
 - Stochastic neural networks (Florensa et al. '17)
 - Reinforcement learning with deep energy-based policies (Haarnoja et al. '17)
 - See lecture on unsupervised information-theoretic exploration
 - many others...

Where does the supervision come from?

- If you want to learn from many different tasks, you need to get those tasks somewhere!
- Learn objectives/rewards from demonstration (inverse reinforcement learning)
- Generate objectives automatically?

reinforcement learning agent

what is the reward?

What is the role of the reward function?

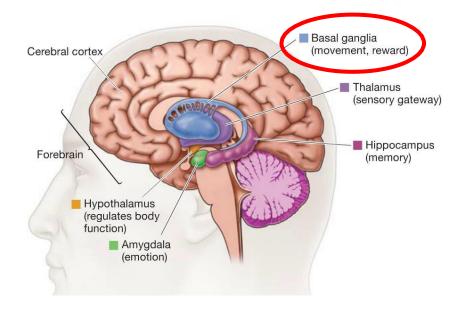

$$r(\mathbf{s}, \mathbf{a}) = \begin{cases} 1 \text{ if walker is running} \\ 0 \text{ otherwise} \end{cases}$$

$$r(\mathbf{s}, \mathbf{a}) = w_1 v(\mathbf{s}) +$$

$$w_2 \delta(|\theta_{\text{torso}}(\mathbf{s})| < \epsilon) +$$

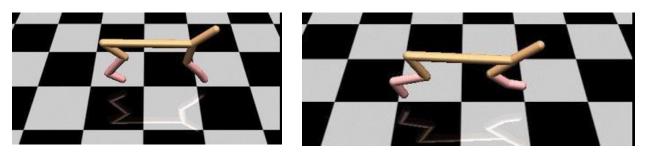

$$w_3 \delta(h_{\text{torso}}(\mathbf{s}) \ge h)$$

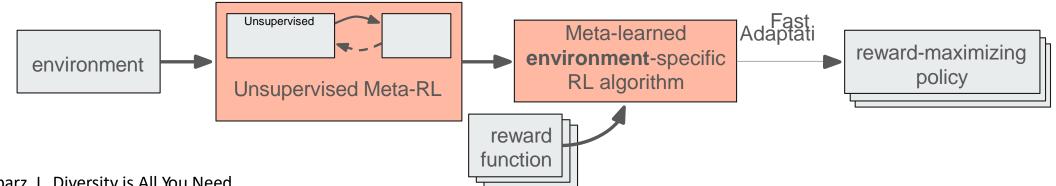

Unsupervised reinforcement learning?

- 1. Interact with the world, without a reward function
- 2. Learn *something* about the world (what?)
- 3. Use what you learned to quickly solve new tasks

Language

• Andreas et al. (2018). Learning with latent language

Human description: move to the star

Inferred description: reach the star cell

Human preferences

• Christiano et al. (2017). Deep reinforcement learning from human preferences

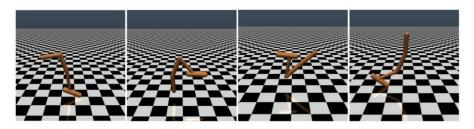

Should supervision tell us **what** to do or **how** to do it?

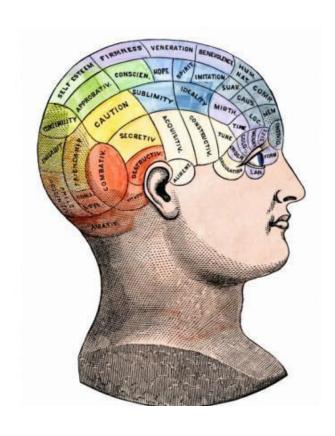

Rethinking the Problem Formulation

- How should we define a control problem?
 - What is the data?
 - What is the goal?
 - What is the supervision?
 - may not be the same as the goal...
- Think about the assumptions that fit your problem setting!
- Don't assume that the basic RL problem is set in stone

Back to the Bigger Picture

Learning as the basis of intelligence

- Reinforcement learning = can reason about decision making
- Deep models = allows RL algorithms to learn and represent complex input-output mappings

Deep models are what allow reinforcement learning algorithms to solve complex problems end to end!

What is missing?

How Much Information Does the Machine Need to Predict?

Y LeCun

"Pure" Reinforcement Learning (cherry)

- The machine predicts a scalar reward given once in a while.
- A few bits for some samples

Supervised Learning (icing)

- ▶ The machine predicts a category or a few numbers for each input
- Predicting human-supplied data
- ▶ 10→10,000 bits per sample

Unsupervised/Predictive Learning (cake)

- The machine predicts any part of its input for any observed part.
- Predicts future frames in videos
- Millions of bits per sample
- (Yes, I know, this picture is slightly offensive to RL folks. But I'll make it up)

Where does the *signal* come from?

- Yann LeCun's cake
 - Unsupervised or self-supervised learning
 - Model learning (predict the future)
 - Generative modeling of the world
 - Lots to do even before you accomplish your goal!
- Imitation & understanding other agents
 - We are social animals, and we have culture for a reason!
- The giant value backup
 - All it takes is one +1
- All of the above

How should we answer these questions?

- Pick the right problems!
- Pay attention to generative models, prediction, etc., not just RL algorithms
- Carefully understand the relationship between RL and other ML fields
