Conclusions

Electre Tri method

1. Define categories using limit profiles $B = \{b_1, b_2, \dots, b_p\}$,

2. Compare a to b_1, b_2, \dots, b_p using an outranking relation S .
3. Assign a to a category C_h according to how a compares to $b_h, h = 1..p$.

Electre Tri method

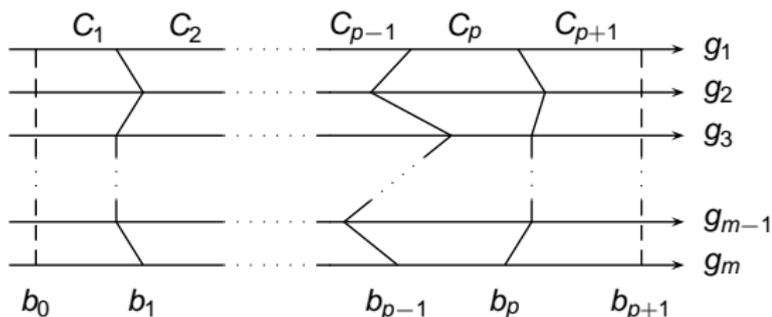

1. Define categories using limit profiles $B = \{b_1, b_2, \dots, b_p\}$,

2. Compare a to b_1, b_2, \dots, b_p using an outranking relation S .
3. Assign a to a category C_h according to how a compares to $b_h, h = 1..p$.

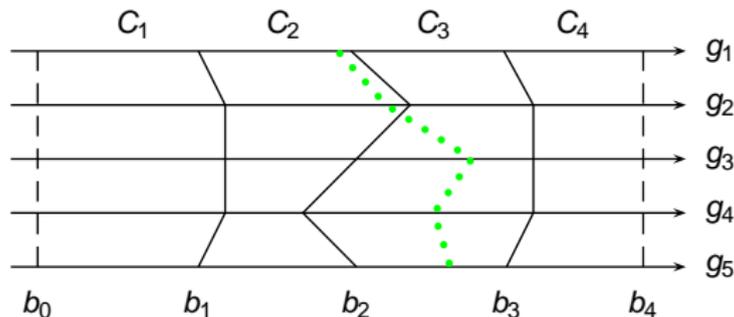

Electre Tri method

1. Define categories using limit profiles $B = \{b_1, b_2, \dots, b_p\}$,

2. Compare a to b_1, b_2, \dots, b_p using an outranking relation S .
3. Assign a to a category C_h according to how a compares to $b_h, h = 1..p$.

Electre Tri method

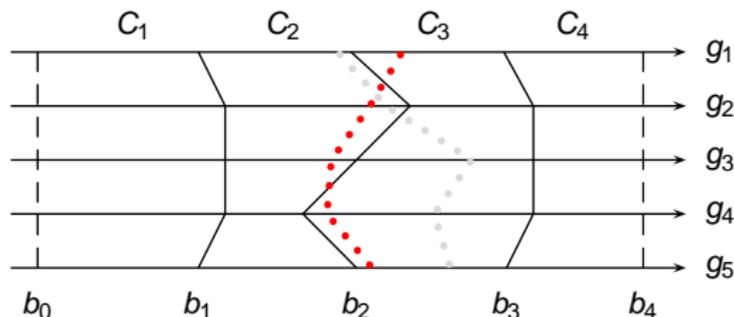

..... a_1 a_2 a_3

| | b_0 | b_1 | b_2 | b_3 | b_4 |
|-------|-------------|-------------|-------------|-------------|-------------|
| a_1 | $a_1 P b_0$ | $a_1 P b_1$ | $a_1 P b_2$ | $b_3 P a_1$ | $b_4 P a_1$ |
| a_2 | | | | | |

- ▶ $Pes(a_1) = C_3$, $Pes(a_2) = C_3$ and $Pes(a_3) = C_2$,
- ▶ $Opt(a_1) = C_3$, $Opt(a_2) = C_3$ and $Opt(a_3) = C_3$,

Electre Tri method

► **Pseudo-conjunctive procedure (pessimistic) :**

- a) Compare a successively to b_i , for $i=p, p-1, \dots, 0$,
- b) Consider b_h the first profile such that aSb_h ,
Assign a to category C_{h+1} .

► **Pseudo-disjonctive procedure (optimistic) :**

- a) Compare a successively to b_i , $i=1, 2, \dots, p+1$,
- b) Consider b_h the first profile b_h such that $b_h \succ a$,
Assign a to category C_h .

- If $Pes(a)$ ($Opt(a)$, resp.) is the assignment category a with the pessimistic procedure (optimistic resp.), it holds:

- $Pes(a) \leq Opt(a)$
- $Pes(a) < Opt(a)$ iff a is incomparable to at least one profile.

Electre Tri method

- ▶ In Electre Tri pessimistic procedure,
 $a \rightarrow C_h$ iff $a \succsim b_{h-1}$ and $\neg(a \succ b_h)$
- ▶ In Electre Tri optimistic procedure,
 $a \rightarrow C_h$ iff $\neg(b_{h-1} \succ a)$ and $b_h \succ b_h$

Conclusions

Elicitation and robustness

- ▶ “Exact knowledge” of $\omega \in \Omega \rightarrow R_{\mathcal{P}}(A, \omega)$,
- ▶ “Incomplete knowledge” on $\Omega(\mathcal{I}) \subset \Omega \rightarrow R_{\mathcal{P}}(A, \Omega(\mathcal{I}))$,
- ▶ $R_{\mathcal{P}}(A, \Omega')$ is the result de \mathcal{P} applied to A considering the “incomplete knowledge” on $\Omega(\mathcal{I}) \subset \Omega$,
- ▶ Computing $R_{\mathcal{P}}(A, \Omega(\mathcal{I}))$ require to develop specific algorithms ([Dias, Climaco 2000], [Greco, Mousseau, Slowinski 2007])

Computing robust assignments

- ▶ [Dias, Clímaco 2000] propose algorithms to compute robust assignments,
- ▶ grounded on the computation of the interval in which $\sigma(a, b_h)$, $a \in A$, $h \in B$ vary knowing \mathcal{I} ,
- ▶ Principle : identify $\max(a, \Omega(\mathcal{I}))$ ($\min(a, \Omega(\mathcal{I}))$, resp.) the index of the best (worst, resp.) category to which a can be assigned considering $\Omega(\mathcal{I})$,

Computing robust assignments

- ▶ $\text{Min}_{\omega \in \Omega(\mathcal{I})} \sigma_d(\mathbf{a}, \mathbf{b}_1) \geq \lambda \Rightarrow \neg(\mathbf{a} \rightarrow \mathbf{C}_1),$
- ▶ $\text{Min}_{\omega \in \Omega(\mathcal{I})} \sigma_d(\mathbf{a}, \mathbf{b}_2) \geq \lambda \Rightarrow \neg(\mathbf{a} \rightarrow \mathbf{C}_2),$
- ▶ ...

- ▶ $\text{Max}_{\omega \in \Omega(\mathcal{I})} \sigma_d(\mathbf{a}, \mathbf{b}_p) < \lambda \Rightarrow \neg(\mathbf{a} \rightarrow \mathbf{C}_p),$
- ▶ $\text{Max}_{\omega \in \Omega(\mathcal{I})} \sigma_d(\mathbf{a}, \mathbf{b}_{p-1}) < \lambda \Rightarrow \neg(\mathbf{a} \rightarrow \mathbf{C}_{p-1}),$
- ▶ ...

→ Hence we can determine that $\mathbf{a} \rightarrow [\mathbf{C}_{min}, \mathbf{C}_{max}]$

Computing robust assignments

```
Begin  
  h ← p (best category)  
  While  $\exists \omega \in \Omega(\mathcal{I}) : \neg(aS_\omega b_{h-1})$   
  Do  
    h ← h-1  
  End While  
   $\min(a, \Omega(\mathcal{I})) \leftarrow h$ 
```

End

```
Begin  
  h ← p (best category)  
  While  $\neg(aS_\omega b_{h-1}), \forall \omega \in \Omega(\mathcal{I})$   
  Do  
    h ← h-1  
  End While  
   $\max(a, \Omega(\mathcal{I})) \leftarrow h$ 
```

End

A short illustrative example

Conclusions

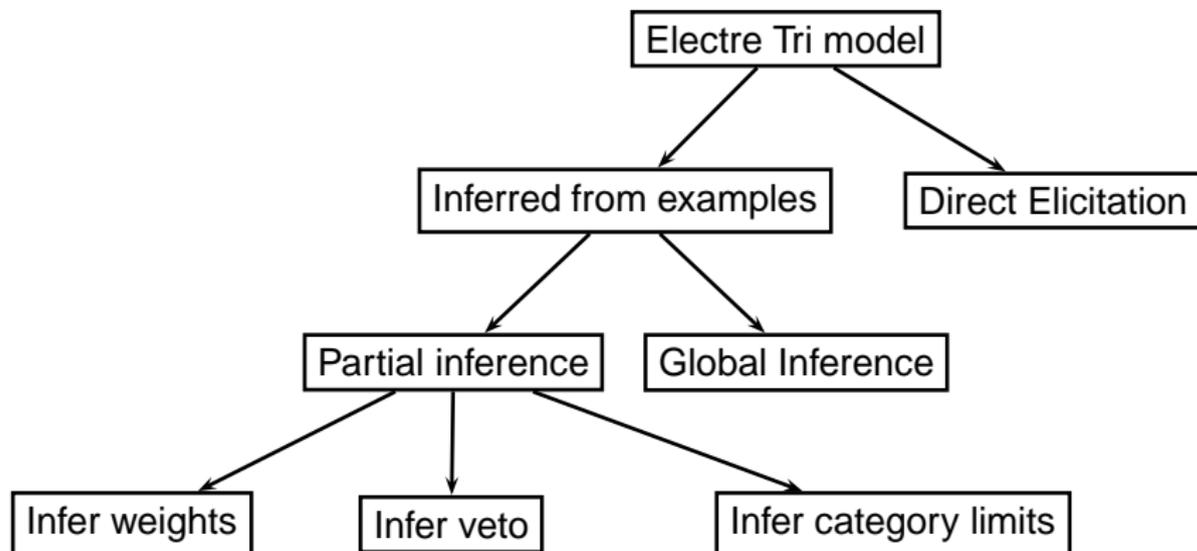

Infer a preference model

- ▶ Inference procedure = algorithm that, starting from an information \mathcal{I} identifies $\omega^*(\mathcal{I})$ which “best match” \mathcal{I} when using \mathcal{P} ,
- ▶ An inference procedure is grounded on the resolution of a mathematical program:
 - ▶ decision variables = parameters to infer,
 - ▶ objective fonction = minimize an “error” fonction (how good \mathcal{I} is accounted for),
 - ▶ constraints = way by which \mathcal{I} is expressed in terms of the preference parameters of \mathcal{P} .

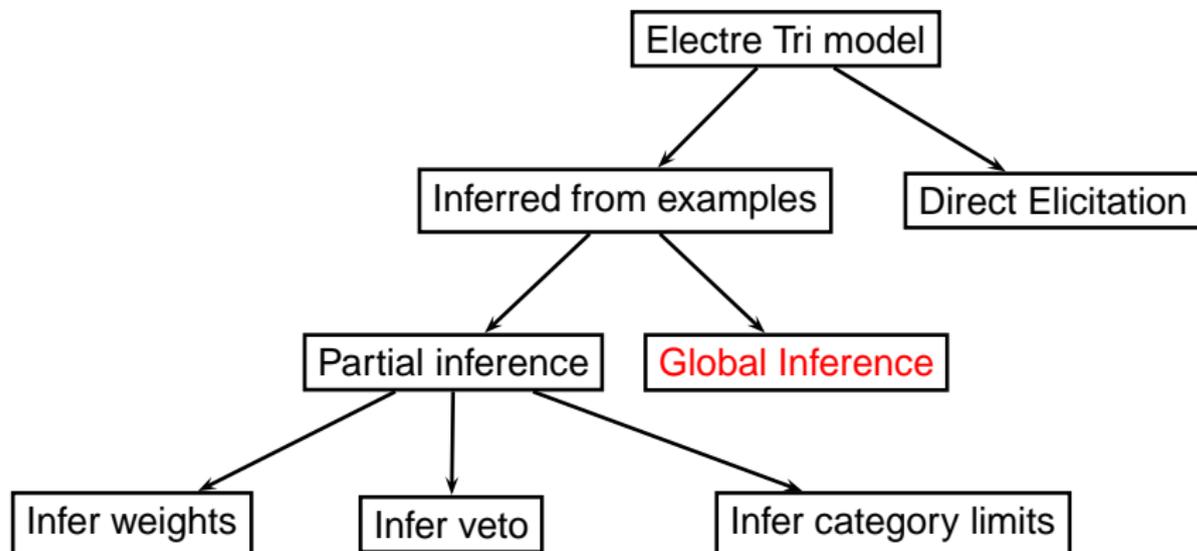

Disaggregation

Inference of an Electre Tri model

Inference of an Electre Tri model

Global inference

- ▶ Consider the assignment example $a \rightarrow_{DM} C_h$,
 $C_h = [b_{h-1}, b_h[$,
- ▶ With Electre Tri pessimistic rule $a \rightarrow C_h \Leftrightarrow aSb_{h-1}$ and $\neg aSb_h$
i.e. $\sigma(a, b_{h-1}) \geq \lambda$ and $\sigma(a, b_h) < \lambda$,
- ▶ x_a and y_a are slack variables defined as:
 $\sigma(a, b_{h-1}) - x_a = \lambda$ and $\sigma(a, b_h) + y_a + \varepsilon = \lambda$, (ε small positive value)
- ▶ If $x_a \geq 0$ and $y_a \geq 0$, then $a \rightarrow C_h, \forall \lambda' \in [\lambda - y_a, \lambda + x_a]$,
- ▶ Consider A^* a set of alternatives for which the DM expresses a desired assignment,
- ▶ If $x_a \geq 0$ and $y_a \geq 0 \forall a \in A^*$, then Electre Tri restores assignment examples in A^* properly.

Global Inference

Max α

$$\text{s.t. } \alpha \leq x_a, \quad \forall a \in A^* \quad (1)$$

$$\alpha \leq y_a, \quad \forall a \in A^* \quad (2)$$

$$\sigma(a, b_{h_a-1}) - x_k = \lambda, \quad \forall a \in A^* \quad (3)$$

$$\sigma(a, b_{h_a}) + y_k + \varepsilon = \lambda, \quad \forall a \in A^* \quad (4)$$

$$\lambda \in [0.5, 1] \quad (5)$$

$$g_j(b_{h+1}) \geq g_j(b_h) + p_j(b_h) + p_j(b_{h+1}), \quad \forall j \in F, \forall h \in B \quad (6)$$

$$v_j(b_h) \geq p_j(b_h) \geq q_j(b_h), \quad \forall j \in F, \forall h \in B \quad (7)$$

$$k_j \geq 0, q_j(b_h) \geq 0, \quad \forall j \in F, \forall h \in B \quad (8)$$

$$\sum_{j \in F} k_j = 1 \quad (9)$$

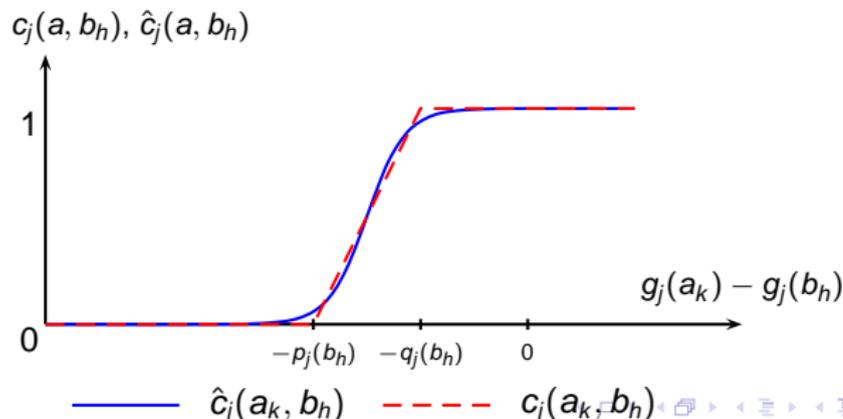

$$\text{all positive variables but } \alpha, x_a, y_a, \quad \forall a \in A^* \quad (10)$$

Global Inference

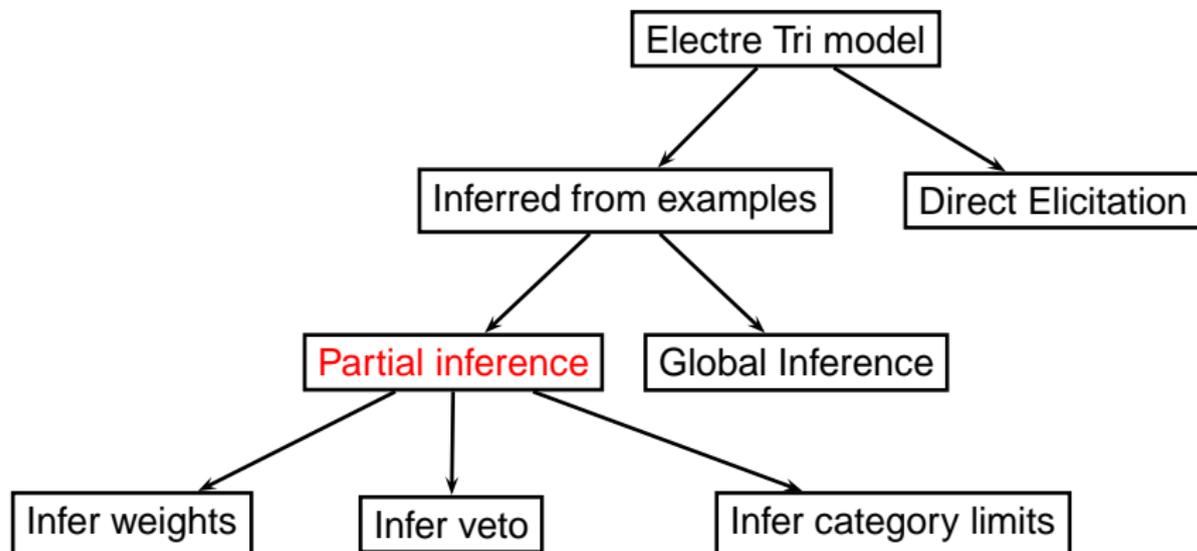

$$\sigma(a, b_h) = C(a, b_h) \times \prod_{j \in \bar{F}} \frac{1 - d_j(a, b_h)}{1 - C(a, b_h)} \text{ où}$$

$$\bar{F} = \{j : d_j(a, b_h) > C(a, b_h)\}$$

$$\hat{c}_j(a, b_h) = \frac{1}{1 + \exp \left[\frac{-5.55}{p_j(b_h) - q_j(b_h)} \cdot \left(g_j(a) - g_j(b_h) + \frac{p_j(b_h) + q_j(b_h)}{2} \right) \right]}$$

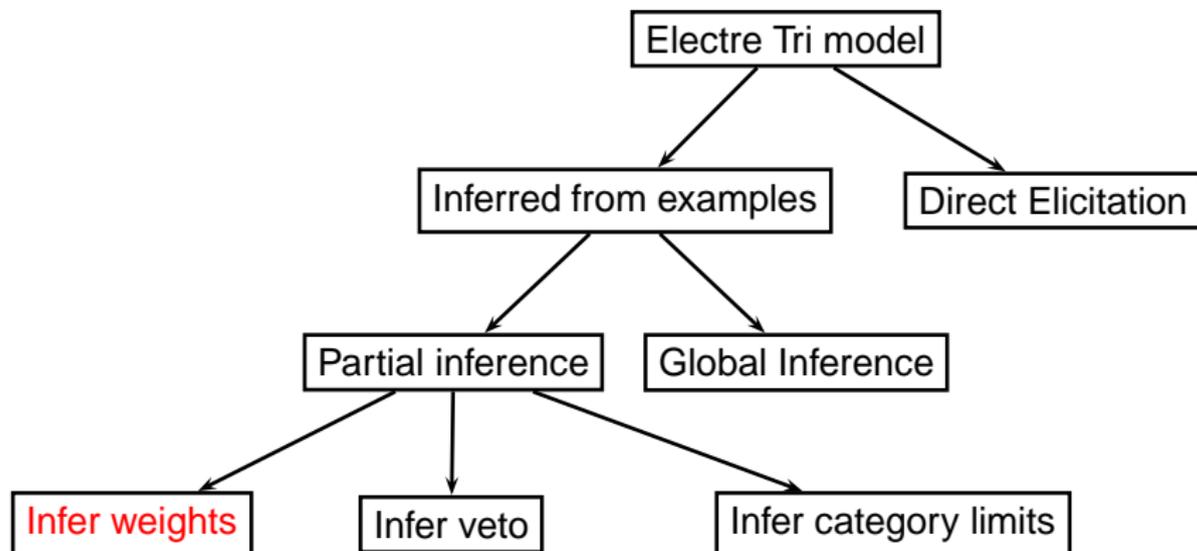

Inference of an Electre Tri model

Partial inference

- ▶ The inference of all parameters leads to large mathematical program for real world problems,
- ▶ To circumvent this difficulty, it is possible to sequentially solve programs which infer a subset of parameters,
- ▶ Problem : optimal value of inferred parameters correspond to values that best match assignment examples **the other parameters being fixed**.

Inference of an Electre Tri model

Inference of k_j and λ

- ▶ if we infer k_j and λ only then inference lead to a linear program,

Max α

$$\text{s.t.} \quad \alpha \leq x_a, \quad \forall a \in A^*$$

$$\alpha \leq y_a, \quad \forall a \in A^*$$

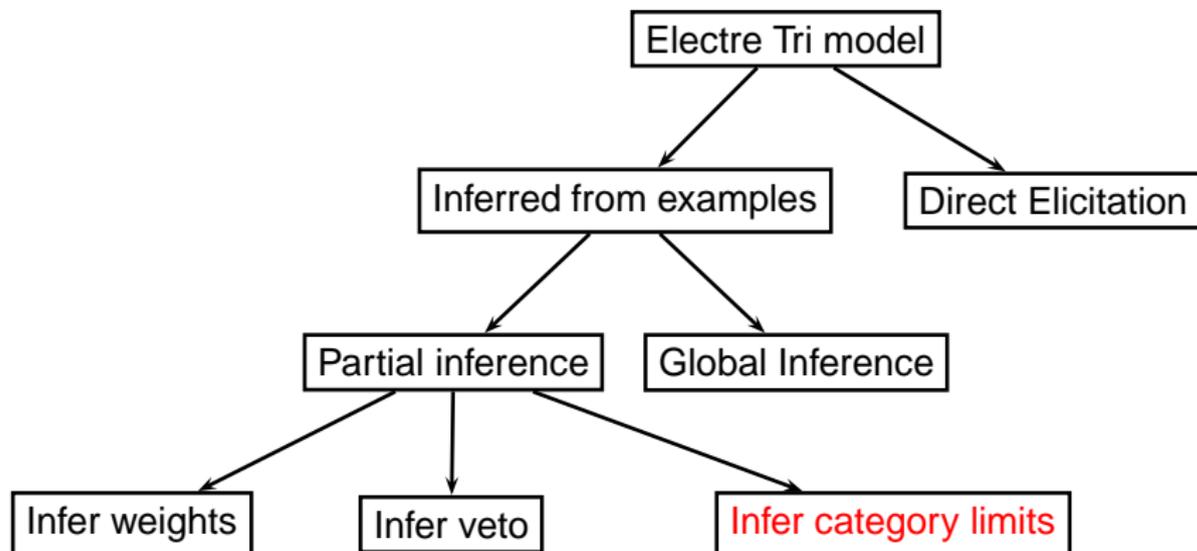

$$\sum_{j \in F} k_j c_j(a, b_{h_a-1}) - x_k = \lambda, \quad \forall a \in A^*$$

$$\sum_{j \in F} k_j c_j(a, b_{h_a}) + y_k + \varepsilon = \lambda, \quad \forall a \in A^*$$

$$\lambda \in [0.5, 1], \quad k_j \geq 0, \quad \forall j \in F, \quad \sum_{j \in F} k_j = 1$$

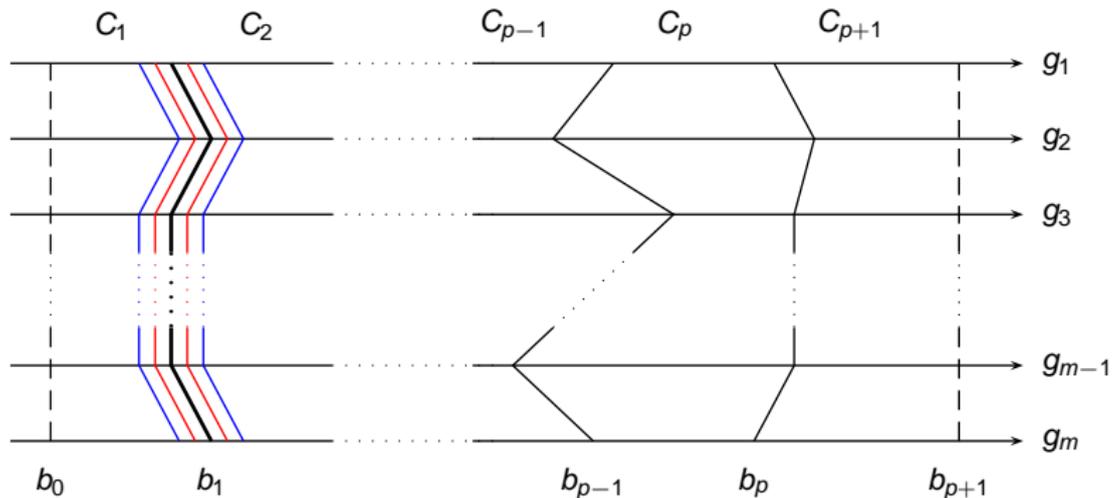

all variables positive but $\alpha, x_a, y_a, \forall a \in A^*$

Inferring an Electre Tri model

Inference of category limits

- Infer values for $g_j(b_h)$, $q_j(b_h)$ and $p_j(b_h)$, $\forall h \in B$, $\forall j \in F$ (the other parameters' values being fixed),

Inference of category limits

- ▶ It is difficult to infer directly the values for $g_j(b_h)$, $q_j(b_h)$ and $p_j(b_h)$, $\forall h \in B$, $\forall j \in F$ (values for k_j and $v_j(b_h)$ being fixed),

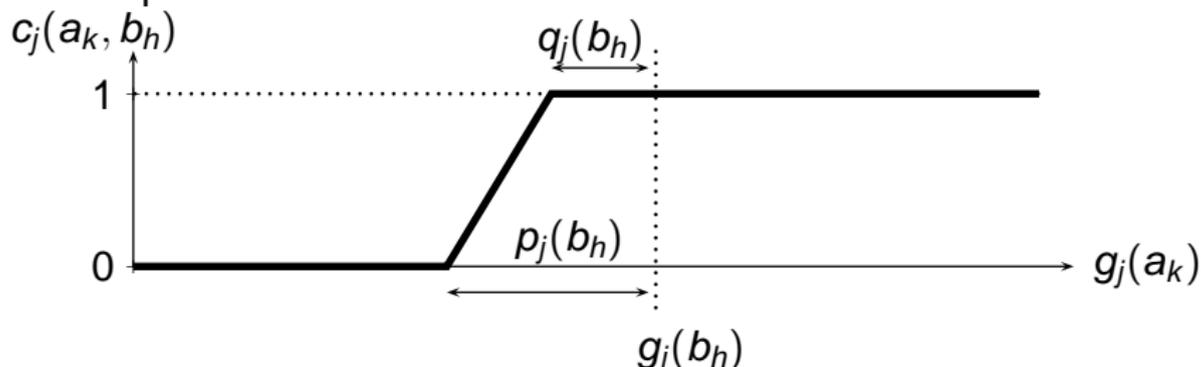

- ▶ 2 successive phases:

Phase 1 : infer how alternatives compare with category limits, i.e., partial concordance indices $c_j(a, b_h)$ and $c_j(b_h, a)$ that best match assignment example,

Phase 2 : determine values for $g_j(b_h)$, $q_j(b_h)$ and $p_j(b_h)$, compatible with partial concordance indices obtained in phase 1.

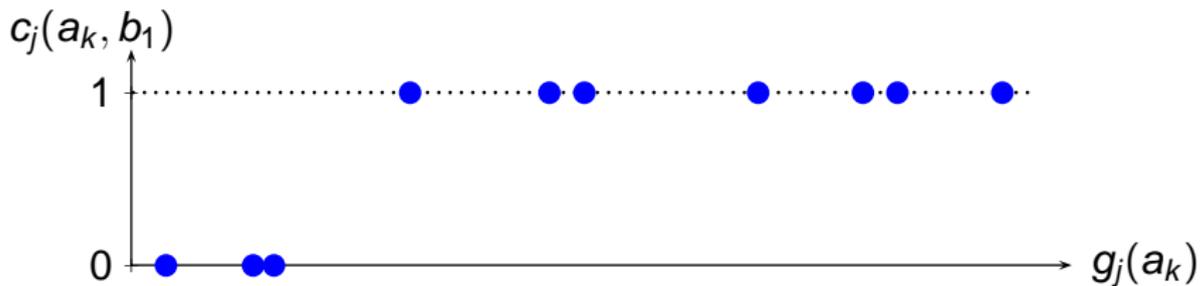

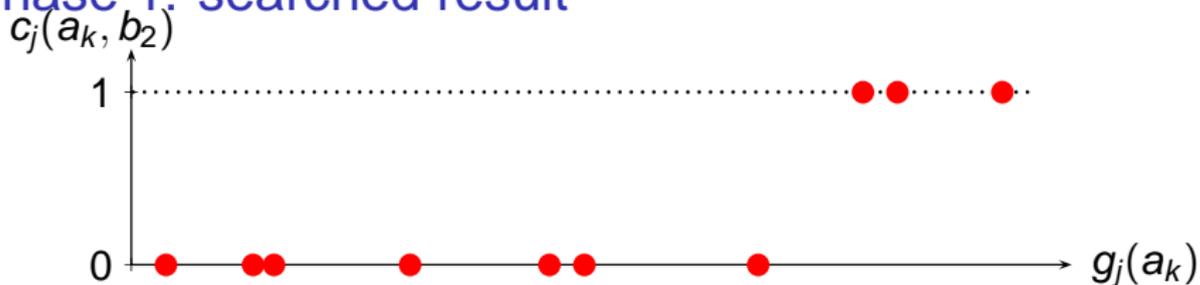

Phase 1

infer how alternatives should compare to profiles (partial concordance indices $c_j(a, b_h)$ and $c_j(b_h, a)$) so that assignment examples are “best” accounted for.

- ▶ $c_j(a_i, b_h) \in [0, 1]$, but almost all values $\in \{0, 1\}$,
- ▶ Variables are $c_j(a_i, b_h)$, λ (majority level) and a slack variable β

Phase 1: searched result

Phase 1

max β

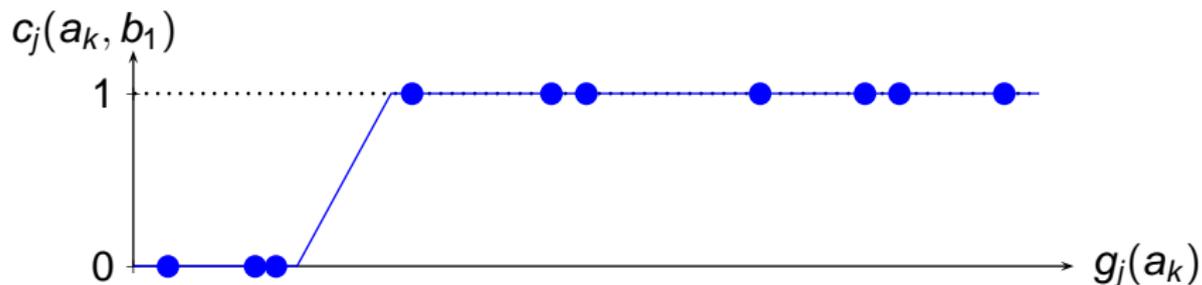

$$\begin{aligned}
 \text{s.t.} \quad & \beta \leq \sum_{j \in F} k_j c_j(a, b_{h_a-1}) - \lambda, \forall a \in A^* \\
 & \beta + \epsilon \leq \lambda - \sum_{j \in F} k_j c_j(a, b_{h_a}), \forall a \in A^* \\
 & \beta + \epsilon \leq \lambda - \sum_{j \in F} k_j c_j(b_{h_a-2}, a), \forall a \in A^* \\
 & 1 \leq c_j(a, b_h) + c_j(b_h, a), \forall j \in F, \forall a \in A^*, h \in B \\
 c_j(a, b_{h+1}) & \leq c_j(a, b_h), \forall j \in F, \forall a \in A^*, h = 1, 2, \dots, p-1 \\
 c_j(b_{h+1}, a) & \geq c_j(b_h, a), \forall j \in F, \forall a \in A^*, h = 1, 2, \dots, p-1 \\
 c_j(a, b_h) & \leq c_j(a', b_h), \forall j \in F, \forall a, a' \in A^*, h \in B, \text{ if } g_j(a) < g_j(a') \\
 c_j(a, b_h) & = c_j(a', b_h), \forall j \in F, \forall a, a' \in A^*, h \in B, \text{ if } g_j(a) = g_j(a') \\
 c_j(b_h, a) & \geq c_j(b_h, a'), \forall j \in F, \forall a, a' \in A^*, h \in B, \text{ if } g_j(a) < g_j(a') \\
 c_j(b_h, a) & = c_j(b_h, a'), \forall j \in F, \forall a, a' \in A^*, h \in B, \text{ if } g_j(a) = g_j(a') \\
 0.5 & \leq \lambda \leq 1 \\
 c_j(a, b_h) & \in \{0, 1\}, \forall j \in F, \forall a \in A^*, h \in B \\
 c_j(b_h, a) & \in \{0, 1\}, \forall j \in F, \forall a \in A^*, h \in B
 \end{aligned}$$

Phase 2

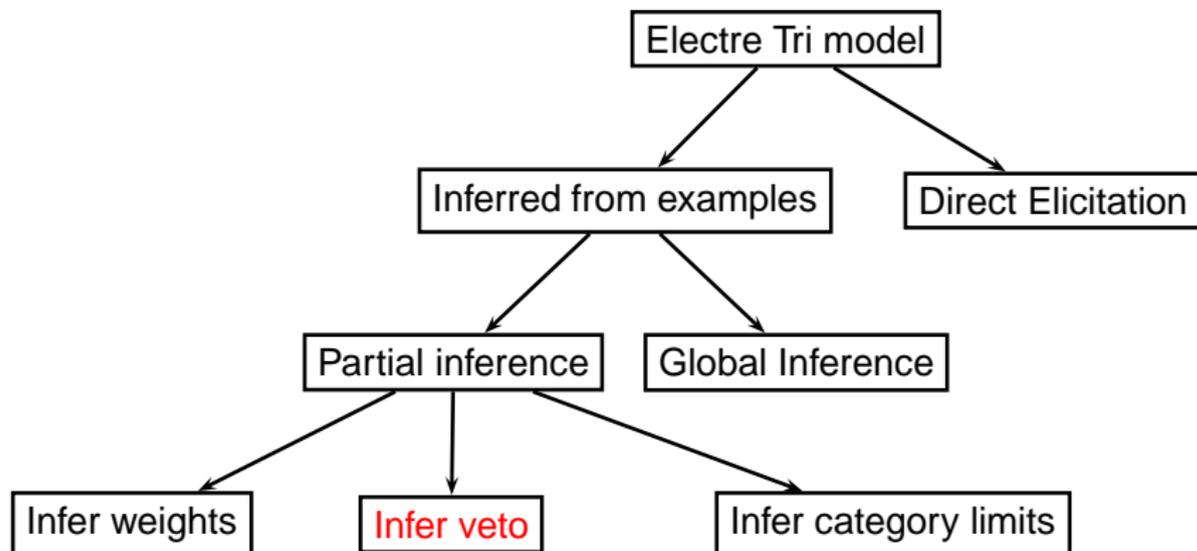

Once $c_j(a_k, b_h)$ and $c_j(b_h, a_k)$ are computed, any values for $g_j(b_h)$, $p_j(b_h)$ and $q_j(b_h)$ verifying the following conditions are acceptable:

- ▶ $c_j(a_k, b_h) = 0 \Rightarrow g_j(b_h) - p_j(b_h) \geq g_j(a_k)$
- ▶ $c_j(a_k, b_h) = 1 \Rightarrow g_j(b_h) - q_j(b_h) \leq g_j(a_k)$
- ▶ $c_j(b_h, a_k) = 0 \Rightarrow g_j(b_h) + p_j(b_h) \leq g_j(a_k)$
- ▶ $c_j(b_h, a_k) = 1 \Rightarrow g_j(b_h) + q_j(b_h) \geq g_j(a_k)$
- ▶ $g_j(b_{h+1}) \geq g_j(b_h)$
- ▶ $p_j(b_h) \geq q_j(b_h) \geq 0$

Phase 2: searched result

Inference of an Electre Tri model

Inference of vetos

- ▶ Infer the veto thresholds $v_j(b_h)$ from assignment examples, the value of the other parameters being fixed,
- ▶ We distinguish cases where:
 - ▶ one single veto threshold is inferred,
 - ▶ several veto thresholds are inferred,

Inference of a single veto

- ▶ All preference parameters are fixed except v_i (supposed constant),

- ▶ Assignment examples induce constraints:

$$\begin{cases} \sigma(a, b_h) \geq \lambda, & \forall a, b_h \text{ t.q. } \text{Cat}_{\min}(a) = h + 1 \\ \sigma(a, b_h) \leq \lambda + \varepsilon, & \forall a, b_h \text{ t.q. } \text{Cat}_{\max}(a) = h \quad \text{or} \\ v_i \geq p_i + \varepsilon \end{cases}$$

$$\begin{aligned} \text{or } \sigma(a, b_h) &= C(a, b_h) \cdot \prod_{j \in \bar{F} \setminus \{i\}} ((1 - d_j(a, b_h))) \cdot (1 - d_i(a, b_h)) \\ &= K_i(a, b_h) \cdot (1 - d_i(a, b_h)) \end{aligned}$$

- ▶ Consider the relation S_{-i} , $aS_{-i}b_h$ means a outranks b_h in absence of veto on g_i , i.e., aSb_h is possible for some values for v_i ,
- $$\begin{aligned} aS_{-i}b_h &\Leftrightarrow K_i(a, b_h) \geq \lambda \\ &\Leftrightarrow (d_j(a, b_h) = 0 \Rightarrow aSb_h) \end{aligned}$$

Inference of a single veto

- ▶ Consider the constraint of the form $\sigma(a, b_h) \geq \lambda$,
 - ▶ if $\neg aS_{-i}b_h$ then it is not possible to find a value for v_i (**inconsistent information**),
 - ▶ if $C(a, b_h) = 1$ then any value for v_i will make the constraint true (**redundant information**)

- ▶ Consider a constraint of the form $\sigma(a, b_h) \leq \lambda + \varepsilon$,
 - ▶ if $C(a, b_h) = 1$ then it is impossible to find a value for v_i (**inconsistent information**),
 - ▶ if $\neg aS_{-i}b_h$ then any value for v_i will make the constraint true (**redundant information**)

Introduction

Problem statements

Electre Tri method

Robust elicitation of a sorting model

Robust assignments

Inference procedures

Inconsistency management

IRIS v2.0: Software illustration

Robust sorting for multiple DMs

Multiple DMs paradigms

Proposed methodology

Private/Collective consistency

Choice of a new assignment example

A short illustrative example

Conclusions

Inconsistency management

- ▶ Consider the ELECTRE TRI method for which the DM is not able to assign precise values for k_j and λ ,
- ▶ Each assignment example induce 2 linear constraints on weights and λ ,
- ▶ → Polyhedron of acceptable values for k_j and λ
- ▶ When the preference information can not be represented in the ELECTRE TRI model, the polyhedron of admissible values for k_j and λ empty
→ inconsistency

Inconsistency management

- ▶ Assignment example define m constraints

$$\begin{cases} \sum_{j=1}^n \alpha_{1j} w_j + \alpha'_1 \lambda & \geq \beta_1 \\ & \vdots \\ \sum_{j=1}^n \alpha_{(m-1)j} w_j + \alpha'_{m-1} \lambda & \geq \beta_{m-1} \\ \sum_{j=1}^n \alpha_{mj} w_j + \alpha'_m \lambda & \geq \beta_m \end{cases} \quad [1]$$

- ▶ Denote $I = \{1, \dots, m\}$; $S \subset I$ solves [1] iff $I \setminus S \neq \emptyset$
- ▶ We look for $S_1, S_2, \dots, S_p \subset I$ such that:
 - (i) S_i solves [1], $i \in \{1, 2, \dots, p\}$;
 - (ii) $S_i \not\subseteq S_j, i, j \in \{1, \dots, p\}, i \neq j$;
 - (iii) $|S_i| \leq |S_j|, i, j \in \{1, 2, \dots, p\}, i < j$;
 - (iv) if $\exists S$ solves [1] s.t. $S \not\subseteq S_i, \forall i = 1, 2, \dots, p$, then $|S| > |S_p|$.

Inconsistency management

- ▶ Consider y_i ($\in \{0, 1\}$, $i \in I$), s.t. :

$$y_i = \begin{cases} 1 & \text{if constraint } i \text{ is deleted} \\ 0 & \text{otherwise} \end{cases}$$

$$P_1 \left\{ \begin{array}{l} \text{Min} \quad \sum_{i \in I} y_i \\ \text{s.t.} \quad \sum_{j=1}^n \alpha_{ij} x_j + \alpha'_i \lambda + M y_i \geq \beta_i, \quad \forall i \in I \\ x_j \geq 0, \quad j = 1, \dots, n \\ y_i \in \{0, 1\}, \quad \forall i \in I \end{array} \right.$$

- ▶ $S_1 = \{i \in I : y_i^* = 1\}$ corresponds to a (or several) subset(s) of constraints solving [1] of smaller cardinality,
- ▶ We define P_2 adding to P_1 the constraint

$$\sum_{i \in S_1} y_i \leq |S_1| - 1$$

Inconsistency management

- ▶ P_{k+1} is defined adding to P_k the constraint $\sum_{i \in S_k} y_i \leq |S_k| - 1$
- ▶ S_1, S_2, \dots, S_k are computed, and the algorithm stops when $|S_{k+1}| > \Omega$ (or when no more solution exists),

```

Begin
  k ← 1
  moresol ← true
  While moresol
    Solve  $PM_k$ 
    If ( $PM_k$  has no solution) or ( $PM_k$  has an optimal value  $> \Omega$ )
      Then moresol ← false
    Else
      -  $S_k \leftarrow \{i \in I : y_i^* = 1\}$ 
      - Add constraint  $\sum_{i \in S_k} y_i \leq |S_k| - 1$  to  $PM_k \rightarrow$  define  $PM_{k+1}$ 
      - k ← k+1
    End if
  End while
End
    
```

Inconsistency management

- ▶ Each S_i corresponds to a set of assignment example (presented to the DM),
- ▶ S_i sets represent “incompatibles” assignment examples, each of them specify a way to solve inconsistency.

Choice of a new assignment example

A short illustrative example

Conclusions

IRIS v2.0: Software illustration

- ▶  implements robust elicitation of an Electre Tri model within a constructive learning perspective,
- ▶ In  learning concerns k_j and λ ,
- ▶  determines robust assignments,
- ▶  detects inconsistencies and proposes alternative solutions to restore consistency,

IRIS v2.0: Software illustration

- ▶ Data required by  as input:
 - ▶ category limits ($g_j(b_h)$, $q_j(b_h)$ and $p_j(b_h)$),
 - ▶ veto thresholds ($v_j(b_h)$),
 - ▶ assignment examples (possibly imprecise)
 - ▶ additional constraints on k_j and λ .

IRIS v2.0: Software illustration

Output information computed by  in the **absence of inconsistency** :

- ▶ a central weight vector that best match the provided information,
- ▶ For each alternative:
 - ▶ its assignment when using the “central” weight vector,
 - ▶ robust assignment, *i.e.*, $[C_{min}(a), C_{max}(a)]$
 - ▶ for each $C_h \in [C_{min}(a), C_{max}(a)]$, weights that lead to the assignment,

IRIS v2.0: Software illustration

Information fournie par  in **presence of inconsistency** :

- ▶ a central weight vector that best match the provided information,
- ▶ For each alternative, its assignment when using the “central” weight vector (even if it differs from the required assignment),
- ▶ a list of minimal subsets of constraints, that if deleted lead to a consistent model.

IRIS v2.0: Software illustration

- ▶ Strategy for use:
 - ▶ accounting for a large number of assignment examples,
 - ▶ progressive integration of assignment examples,

IRIS v2.0 : Example

Assigning students evaluated on 5 dimensions to 4 categories
→ refusal, hesitating refusal, hesitating acceptance, acceptance.

| a_{12} | 15 | 10 | 11 | 18 | 8 |
| a_{13} | 18 | 10 | 1 | 15 | 8 |
| a_{14} | 19 | 16 | 16 | 11 | 8 |

IRIS v2.0 : Example

progressive integration of assignment examples,

- ▶ $a_8 \rightarrow [C_3, C_4]$,
- ▶ $a_{14} \rightarrow C_4$,
- ▶ $a_5 \rightarrow [C_1, C_2]$,
- ▶ $k_4 \geq 0.01$
- ▶ $k_1 \geq 0.33$
- ▶ $a_7 \rightarrow [C_1, C_2]$ (inconsistency),

IRIS v2.0 : Example

accounting for a large number of assignment examples,

- ▶ $a_0 \rightarrow C_1$,
- ▶ $a_1 \rightarrow [C_3, C_4]$ (error judgment),
- ▶ $a_2 \rightarrow C_3$,
- ▶ $a_3 \rightarrow C_1$,
- ▶ $a_6 \rightarrow [C_1, C_2]$,
- ▶ $a_{10} \rightarrow [C_3, C_4]$,
- ▶ $a_{12} \rightarrow C_4$

Conclusions

Proposed methodology

In the proposed methodology:

- ▶ DMs agree on the evaluation criteria,
- ▶ DMs consider the same set A and evaluation table,
- ▶ DMs agree on the definition of categories, thus on limit profiles,
- ▶ DMs interact on assignment examples,
- ▶ Aggregation/disaggregation principles support interaction,
- ▶ DMs refine the information iteratively.

Two main difficulties arise:

- ▶ Possible disagreement on assignment examples among DMs,
- ▶ Finding an agreement on assignment examples that is consistent.

Proposed methodology

In the proposed methodology:

- ▶ DMs agree on the evaluation criteria,
- ▶ DMs consider the same set A and evaluation table,

Two main difficulties arise:

- ▶ Possible disagreement on assignment examples among DMs,
- ▶ Finding an agreement on assignment examples that is consistent.

Proposed methodology

The proposed methodology accounts for these two issues:

- ▶ The necessity to make DMs converge toward a collective set of robust assignments and finally a common set of inferred parameters,
- ▶ The necessity to make DMs being and staying collectively as well as individually consistent.

Proposed methodology

The proposed methodology accounts for these two issues:

- ▶ The necessity to make DMs converge toward a collective set of robust assignments and finally a common set of inferred parameters,
- ▶ The necessity to make DMs being and staying collectively as well as individually consistent.

Proposed methodology

- ▶ Two level are identified :
 - ▶ k individual models
 - ▶ 1 collective model
- ▶ Each individual model is defined by:
 - ▶ a set of assignment examples \mathcal{I} ,
 - ▶ the corresponding $\Omega(\mathcal{I})$, $R(A, \Omega(\mathcal{I}))$ and $\omega^*(\mathcal{I}) \in \Omega(\mathcal{I})$,
- ▶ Each DM starts with an individual (consistent) model,
- ▶ In the iterative process, the collective model is build progressively by integrating assignment examples,
- ▶ At each iteration, each individual model should be consistent and compatible with the collective model.

Proposed methodology

- ▶ Two level are identified :
 - ▶ k individual models
 - ▶ 1 collective model
- ▶ Each individual model is defined by:
 - ▶ a set of assignment examples \mathcal{I} ,
 - ▶ the corresponding $\Omega(\mathcal{I})$, $R(A, \Omega(\mathcal{I}))$ and $\omega^*(\mathcal{I}) \in \Omega(\mathcal{I})$,

- ▶ Each DM starts with an individual (consistent) model,
- ▶ In the iterative process, the collective model is build progressively by integrating assignment examples,
- ▶ At each iteration, each individual model should be consistent and compatible with the collective model.

Proposed methodology

- ▶ *Step 1:*
 - Each DM defines a consistent set of assign. examples
 - The collective model has no assignment example
($Min(a_i) = C_1, Max(a_i) = C_n$)
- ▶ *Step 2:* DMs discuss in order to agree on an assign. example
- ▶ *Step 3:* The agreed assignment example is incorporated in the collective model and in each individual model (each DM may privately revise inputs by deleting/modifying examples). New robust assignments are computed for each DM.
- ▶ *Step 4:* If the collective model is satisfactory or no further agreement can be found, then Stop, else go to step 2

Proposed methodology

- ▶ *Step 1:*
 - Each DM defines a consistent set of assign. examples
 - The collective model has no assignment example
($Min(a_i) = C_1, Max(a_i) = C_n$)
- ▶ *Step 2:* DMs discuss in order to agree on an assign. example
- ▶ *Step 3:* The agreed assignment example is incorporated in the collective model and in each individual model (each DM may privately revise inputs by deleting/modifying examples). New robust assignments are computed for each DM.
- ▶ *Step 4:* If the collective model is satisfactory or no further agreement can be found, then Stop, else go to step 2

Proposed methodology

- ▶ *Step 4:* If the collective model is satisfactory or no further agreement can be found, then Stop, else go to step 2.

Proposed methodology

- ▶ Initially in the collective model $C_{min}(a_i) = C_1$, $C_{max}(a_i) = C_n, \forall a_i$ and the procedure aims, at each iteration, at narrowing the possible assignments of alternatives,
- ▶ A consensus on an assignment example a_i introduces constraints on the parameter values...
- ▶ ... which constrain the interval of possible assignments $[C_{min}(a_j), C_{max}(a_j)]$ for $a_j \neq a_i$
- ▶ The process stops when each alternative is assigned to a single category or further consensus is difficult to reach.

Proposed methodology

Conclusions

Individual/Collective consistency

How to make each individual model consistent with the new assignment example ?

- ▶ Suppose all DMs state $a_i \rightarrow C_1$ except DM_1 $a_i \rightarrow C_2$,
- ▶ DM_1 can make a concession $a_i \rightarrow C_1$ if he/she accept all consequences in his/her individual model on all assignment ranges:
 - ▶ $a_i \rightarrow C_1$ can narrow the assignment range of some other alternatives
 - ▶ $a_i \rightarrow C_1$ can contradict an assignment example of the DM_1 's private model

Individual/Collective consistency

How to make each individual model consistent with the new assignment example ?

Choice of a new assignment example

A short illustrative example

Conclusions

Choice of a new assignment example

How to choose, at each iteration, a new assignment example?

- ▶ $E_k(a_i, C_x) = 1$ if $C_x \in [C_{min}^k(a_i), C_{max}^k(a_i)]$
= 0 otherwise
- ▶ $E(a_i, C_x) = \frac{\sum_{k=1}^K E_k(a_i, C_x)}{K}$, majority level for $a_i \rightarrow C_x$
- ▶ number of “shifts”: changing from $a_i \rightarrow C_1$ to $a_i \rightarrow C_3$ is stronger than changing from $a_i \rightarrow C_1$ to $a_i \rightarrow C_2$)

Choice of a new assignment example

How to choose, at each iteration, a new assignment example?

- ▶ $E_k(a_i, C_x) = 1$ if $C_x \in [C_{min}^k(a_i), C_{max}^k(a_i)]$

Conclusions

Conclusion

- ▶ Constructive elicitation of a robust ELECTRE TRI sorting model,
- ▶ Account for multiple DMs setting,
- ▶ Other elicitation tools need to be designed with respect to MCAPs,
- ▶ Plenty of work is to be done to design such elicitation tools.
- ▶ Software implementations,
